#### Logistics

Thanks for info on final project ideas.

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ● ● ●

HW 2 due Monday!

## Life lessons from HW 2?

Where an error occurs may not be where you observe it!

(ロ) (同) (三) (三) (三) (三) (○) (○)

- Check against a slow, naive, obvious calculation.
- assert is your friend.
- Use version control (git, cvs, svn, ...).

#### Reminder: Conjugate Gradients

What if we only know how to multiply by *A*? About all you can do is keep multiplying!

$$\mathcal{K}_k(A,b) = \operatorname{span}\left\{b, Ab, A^2b, \dots, A^{k-1}b\right\}.$$

Gives surprisingly useful information!

If A is symmetric and positive definite,  $x = A^{-1}b$  minimizes

$$\phi(x) = \frac{1}{2}x^T A x - x^T b$$
$$\nabla \phi(x) = A x - b.$$

Idea: Minimize  $\phi(x)$  over  $\mathcal{K}_k(A, b)$ . Basis for the *method of conjugate gradients* 

## Convergence of CG

- KSPs are not stationary (no constant fixed-point iteration)
- Convergence is surprisingly subtle!
- CG convergence upper bound via *condition number* 
  - Large condition number iff form  $\phi(x)$  has long narrow bowl

(日) (日) (日) (日) (日) (日) (日)

- Usually happens for Poisson and related problems
- Preconditioned problem  $M^{-1}Ax = M^{-1}b$  converges faster?
- ► Whence *M*?
  - From a stationary method?
  - From a simpler/coarser discretization?
  - From approximate factorization?

# PCG

Compute 
$$r^{(0)} = b - Ax$$
  
for  $i = 1, 2, ...$   
solve  $Mz^{(i-1)} = r^{(i-1)}$   
 $\rho_{i-1} = (r^{(i-1)})^T z^{(i-1)}$   
if  $i == 1$   
 $p^{(1)} = z^{(0)}$   
else  
 $\beta_{i-1} = \rho_{i-1}/\rho_{i-2}$   
 $p^{(i)} = z^{(i-1)} + \beta_{i-1}p^{(i-1)}$   
endif  
 $q^{(i)} = Ap^{(i)}$   
 $\alpha_i = \rho_{i-1}/(p^{(i)})^T q^{(i)}$   
 $x^{(i)} = x^{(i-1)} + \alpha_i p^{(i)}$   
 $r^{(i)} = r^{(i-1)} - \alpha_i q^{(i)}$ 

end

Parallel work:

- Solve with M
- Product with A
- Dot products
- Axpys

Overlap comm/comp.

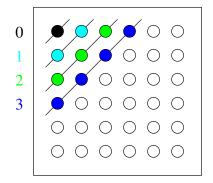

## PCG bottlenecks

Key: fast solve with M, product with A

- Some preconditioners parallelize better! (Jacobi vs Gauss-Seidel)
- Balance speed with performance.
  - Speed for set up of M?
  - Speed to apply M after setup?
- Cheaper to do two multiplies/solves at once...
  - Can't exploit in obvious way lose stability
  - Variants allow multiple products Hoemmen's thesis
- ► Lots of fiddling possible with *M*; what about matvec with *A*?

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ● のへで

# Thinking on (basic) CG convergence

Consider 2D Poisson with 5-point stencil on an  $n \times n$  mesh.

- Information moves one grid cell per matvec.
- Cost per matvec is O(n<sup>2</sup>).
- At least O(n<sup>3</sup>) work to get information across mesh!

## CG convergence: a counting approach

- Time to converge ≥ time to propagate info across mesh
- For a 2D mesh: O(n) matvecs,  $O(n^3) = O(N^{3/2})$  cost
- For a 3D mesh: O(n) matvecs,  $O(n^4) = O(N^{4/3})$  cost

(日) (日) (日) (日) (日) (日) (日)

- "Long" meshes yield slow convergence
- 3D beats 2D because everything is closer!
  - Advice: sparse direct for 2D, CG for 3D.
  - Better advice: use a preconditioner!

#### CG convergence: an eigenvalue approach

Define the *condition number* for  $\kappa(L)$  s.p.d:

$$\kappa(L) = rac{\lambda_{\mathsf{max}}(L)}{\lambda_{\mathsf{min}}(L)}$$

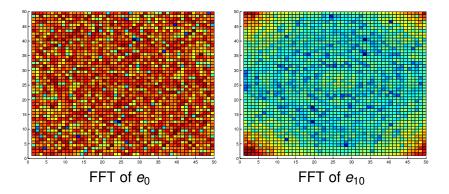

Describes how elongated the level surfaces of  $\phi$  are.

For Poisson, 
$$\kappa(L) = O(h^{-2})$$

• CG steps to reduce error by  $1/2 = O(\sqrt{\kappa}) = O(h^{-1})$ .

Similar back-of-the-envelope estimates for some other PDEs. But these are not always that useful... can be pessimistic if there are only a few extreme eigenvalues.

## CG convergence: a frequency-domain approach

Error  $e_k$  after k steps of CG gets smoother!

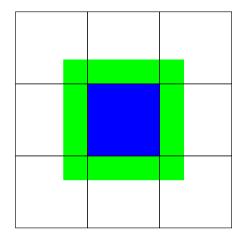

イロト イポト イヨト イヨト

# Choosing preconditioners for 2D Poisson

- CG already handles high-frequency error
- Want something to deal with lower frequency!
- Jacobi useless
  - Doesn't even change Krylov subspace!
- Better idea: block Jacobi?
  - Q: How should things split up?
  - A: Minimize blocks across domain.
  - Compatible with minimizing communication!

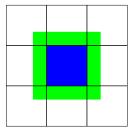

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

#### Restrictive Additive Schwartz (RAS)

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

# Restrictive Additive Schwartz (RAS)

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

- Get ghost cell data
- Solve everything local (including neighbor data)
- Update local values for next step
- Default strategy in PETSc

#### **Multilevel Ideas**

- RAS propogates information by one processor per step
- For scalability, still need to get around this!
- Basic idea: use multiple grids
  - Fine grid gives lots of work, kills high-freq error
  - Coarse grid cheaply gets info across mesh, kills low freq

(ロ) (同) (三) (三) (三) (三) (○) (○)

More on this another time.

# CG performance

Two ways to get better performance from CG:

- 1. Better preconditioner
  - Improves asymptotic complexity?
  - ... but application dependent
- 2. Tuned implementation
  - Improves constant in big-O
  - ... but application independent?

Benchmark idea (?): no preconditioner, just tune.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

# **Tuning PCG**

```
Compute r^{(0)} = b - Ax
for i = 1, 2, ...
     solve Mz^{(i-1)} = r^{(i-1)}
     \rho_{i-1} = (r^{(i-1)})^T z^{(i-1)}
     if i == 1
        p^{(1)} = z^{(0)}
     else
        \beta_{i-1} = \rho_{i-1}/\rho_{i-2}
        p^{(i)} = z^{(i-1)} + \beta_{i-1} p^{(i-1)}
     endif
     a^{(i)} = A p^{(i)}
     \alpha_{i} = \rho_{i-1} / (p^{(i)})^{T} q^{(i)}
     x^{(i)} = x^{(i-1)} + \alpha_i p^{(i)}
     \mathbf{r}^{(i)} = \mathbf{r}^{(i-1)} - \alpha_i \mathbf{q}^{(i)}
end
```

- Most work in A, M
- Vector ops synchronize
- Overlap comm, comp?

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

# **Tuning PCG**

Compute  $r^{(0)} = b - Ax$  $p_{-1} = 0; \beta_{-1} = 0; \alpha_{-1} = 0$  $s = l^{-1} r^{(0)}$  $\rho_0 = \mathbf{s}^T \mathbf{s}$ for i = 0, 1, 2, ... $W_i = L^{-T} s$  $\mathcal{D}_i = \mathcal{W}_i + \beta_{i-1} \mathcal{D}_{i-1}$  $q_i = A p_i$  $\gamma = \boldsymbol{p}_i^T \boldsymbol{q}_i$  $x_i = x_{i-1} + \alpha_{i-1} p_{i-1}$  $\alpha_i = \rho_i / \gamma_i$  $r_{i+1} = r_i - \alpha q_i$  $s = L^{-1}r_{i+1}$  $\rho_{i+1} = \mathbf{s}^T \mathbf{s}$ Check convergence  $(||r_{i+1}||)$  $\beta_i = \rho_{i+1}/\rho_i$ end

Split  $z = M^{-1}r$  into  $s, w_i$ Overlap

- $p_i^T q_i$  with x update
- $s^T s$  with  $w_i$  eval
- Computing  $p_i$ ,  $q_i$ ,  $\gamma$
- Pipeline r<sub>i+1</sub>, s?
- Pipeline  $p_i$ ,  $w_i$ ?

Parallel Numerical LA, Demmel, Heath, van der Vorst

# **Tuning PCG**

Can also tune

- Preconditioner solve (hooray!)
- Matrix multiply
  - Represented implicitly (regular grids)
  - Or explicitly (e.g. compressed sparse column)

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Or further rearrange algorithm (Hoemmen, Demmel).

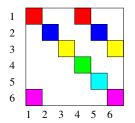

## Tuning sparse matvec

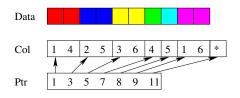

Sparse matrix blocking and reordering (Im, Vuduc, Yelick)

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- Packages: Sparsity (Im), OSKI (Vuduc)
- Available as PETSc extension
- Optimizing stencil operations (Datta)

## Reminder: Compressed sparse row storage

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Problem: y[i] += A[jj] \*x[col[j]];

# Memory traffic in CSR multiply

Memory access patterns:

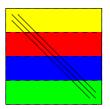

- Elements of y accessed sequentially
- Elements of A accessed sequentially
- Access to x are all over!

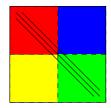

Can help by switching to block CSR.

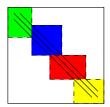

Switching to single precision, short indices can help memory traffic, too!

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

# Parallelizing matvec

- Each processor gets a piece
- Many partitioning strategies
- Idea: re-order so one of these strategies is "good"

# Reordering for matvec

SpMV performance goals:

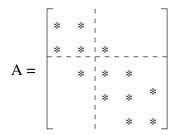

- Balance load?
- Balance storage?
- Minimize communication?
- Good cache re-use?

Also reorder for

- Stability of Gauss elimination,
- Fill reduction in Gaussian elimination,
- Improved performance of preconditioners...

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

# Reminder: Sparsity and partitioning

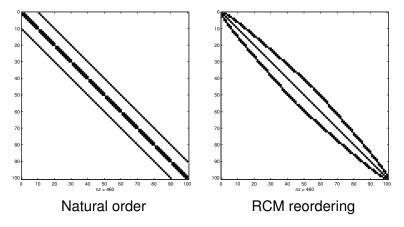

Want to partition sparse graphs so that

- Subgraphs are same size (load balance)
- Cut size is minimal (minimize communication)

Matrices that are "almost" diagonal are good?

# Reordering for bandedness

#### Reverse Cuthill-McKee

- Select "peripheral" vertex v
- Order according to breadth first search from v

・ ロ ト ・ 雪 ト ・ 雪 ト ・ 日 ト

3

Reverse ordering

## From iterative to direct

- RCM ordering is great for SpMV
- But isn't narrow banding good for solvers, too?
  - LU takes  $O(nb^2)$  where b is bandwidth.
  - Great if there's an ordering where b is small!

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

## Skylines and profiles

- Profile solvers generalize band solvers
- Use skyline storage; if storing lower triangle, for each row i:

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

- Start and end of storage for nonzeros in row.
- Contiguous nonzero list up to main diagonal.
- In each column, first nonzero defines a profile.
- All fill-in confined to profile.
- RCM is again a good ordering.

## **Beyond bandedness**

#### Bandedness only takes us so far

Minimum bandwidth for 2D model problem? 3D?

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

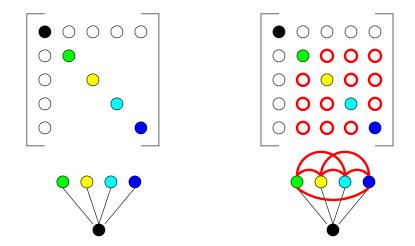

- Skyline only gets us so much farther
- But more general solvers have similar structure
  - Ordering (minimize fill)
  - Symbolic factorization (where will fill be?)
  - Numerical factorization (pivoting?)
  - ... and triangular solves

## Reminder: Matrices to graphs

- $A_{ij} \neq 0$  means there is an edge between *i* and *j*
- Ignore self-loops and weights for the moment
- Symmetric matrices correspond to undirected graphs

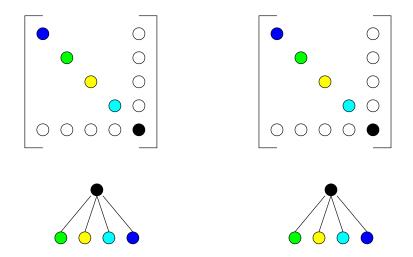

(ロ) (同) (三) (三) (三) (○) (○)

## **Troublesome Trees**

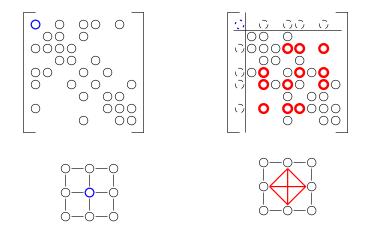

One step of Gaussian elimination completely fills this matrix!

## **Terrific Trees**

Full Gaussian elimination generates no fill in this matrix!

# **Graphic Elimination**

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Eliminate a variable, connect all neighbors.

# **Graphic Elimination**

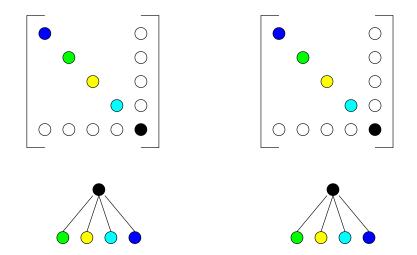

#### Consider first steps of GE

```
A(2:end,1) = A(2:end,1)/A(1,1);
A(2:end,2:end) = A(2:end,2:end)-...
A(2:end,1)*A(1,2:end);
```

Nonzero in the outer product at (i, j) if A(i, 1) and A(j, 1) both nonzero — that is, if *i* and *j* are both connected to 1.

General: Eliminate variable, connect remaining neighbors.

# **Terrific Trees Redux**

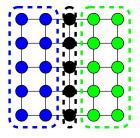

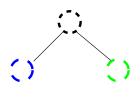

Order leaves to root  $\implies$  on eliminating *i*, parent of *i* is only remaining neighbor.

・ロン ・四 と ・ ヨ と ・ ヨ と

э.

## **Nested Dissection**

- ▶ Idea: Think of *block* tree structures.
- Eliminate block trees from bottom up.
- Can recursively partition at leaves.
- Rough cost estimate: how much just to factor dense Schur complements associated with separators?
- Notice graph partitioning appears again!
  - And again we want small separators!

#### **Nested Dissection**

Model problem: Laplacian with 5 point stencil (for 2D)

 ND gives optimal complexity in exact arithmetic (George 73, Hoffman/Martin/Rose)

(日) (日) (日) (日) (日) (日) (日)

- > 2D:  $O(N \log N)$  memory,  $O(N^{3/2})$  flops
- ▶ 3D: O(N<sup>4/3</sup>) memory, O(N<sup>2</sup>) flops

## Minimum Degree

Locally greedy strategy

- Want to minimize upper bound on fill-in
- ► Fill ≤ (degree in remaining graph)<sup>2</sup>
- At each step
  - Eliminate vertex with smallest degree
  - Update degrees of neighbors
- Problem: Expensive to implement!
  - But better varients via quotient graphs

(日) (日) (日) (日) (日) (日) (日)

Variants often used in practice

## **Elimination Tree**

- Variables (columns) are nodes in trees
- j a descendant of k if eliminating j updates k

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Can eliminate disjoint subtrees in parallel!

Basic idea: exploit "supernodal" (dense) structures in factor

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- e.g. arising from elimination of separator Schur complements in ND
- Other alternatives exist (multifrontal solvers)

# Pivoting

Pivoting is a tremendous pain, particularly in distributed memory!

- Cholesky no need to pivot!
- Threshold pivoting pivot when things look dangerous
- Static pivoting try to decide up front

What if things go wrong with threshold/static pivoting? Common theme: Clean up sloppy solves with good residuals

(ロ) (同) (三) (三) (三) (○) (○)

## Direct to iterative

Can improve solution by iterative refinement:

$$PAQ \approx LU$$

$$x_0 \approx QU^{-1}L^{-1}Pb$$

$$r_0 = b - Ax_0$$

$$x_1 \approx x_0 + QU^{-1}L^{-1}Pr_0$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Looks like approximate Newton on F(x) = Ax - b = 0. This is just a stationary iterative method! Nonstationary methods work, too.

#### Variations on a theme

If we're willing to sacrifice some on factorization,

Single precision + refinement on double precision residual?

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

- Sloppy factorizations (marginal stability) + refinement?
- Modify m small pivots as they're encountered (low rank updates), fix with m steps of a Krylov solver?
