

Trees

Lecture 9
CS2110 – Fall 2008

Announcements

- A3 will be up shortly – check the website
- A2 is graded
 - Submit regrades online
 - Regrades accepted until 10/3
- Please include Cornell netid in email correspondence
 - e.g., dancingGur147@gmail.com does not help us

2

Tree Overview

- **Tree:** recursive data structure (similar to list)
 - Each cell may have zero or more successors (children)
 - Each cell has exactly one predecessor (parent) except the root, which has none
 - All cells are reachable from root
- **Binary tree:** tree in which each cell can have at most two children: a left child and a right child

3

Tree Terminology

- M is the **root** of this tree
- G is the **root** of the **left subtree** of M
- B, H, J, N, and S are **leaves**
- N is the **left child** of P; S is the **right child**
- P is the **parent** of N
- M and G are **ancestors** of D
- P, N, and S are **descendants** of W
- Node J is at **depth 2** (i.e., **depth** = length of path from root = number of edges)
- Node W is at **height 2** (i.e., **height** = length of longest path to a leaf)
- A collection of several trees is called a ...?

4

Class for Binary Tree Cells

```
class TreeCell<T> {
  private T datum;
  private TreeCell<T> left, right;

  public TreeCell(T x) { datum = x; }
  public TreeCell(T x, TreeCell<T> lft,
                 TreeCell<T> rgt) {
    datum = x;
    left = lft;
    right = rgt;
  }
  more methods: getDatum, setDatum,
  getLeft, setLeft, getRight, setRight
}
```

```
... new TreeCell<String>("hello") ...
```

5

Class for General Trees

```
class GTreeCell {
  private Object datum;
  private GTreeCell left;
  private GTreeCell sibling;

  appropriate getter and
  setter methods
}
```

General tree

- Parent node points directly only to its leftmost child
- Leftmost child has pointer to next sibling, which points to next sibling, etc.

Tree represented using GTreeCell

6

Applications of Trees

- Most languages (natural and computer) have a recursive, hierarchical structure
- This structure is *implicit* in ordinary textual representation
- Recursive structure can be made *explicit* by representing sentences in the language as trees: **Abstract Syntax Trees (ASTs)**
- ASTs are easier to optimize, generate code from, etc. than textual representation
- A **parser** converts textual representations to AST

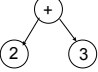

7

Example

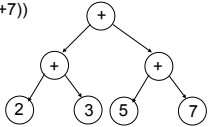

- Expression grammar:
 $E \rightarrow \text{integer}$
 $E \rightarrow (E + E)$

Text AST Representation

-34 (-34)

(2 + 3) 

- In textual representation
 - Parentheses show hierarchical structure

((2+3) + (5+7)) 

- In tree representation
 - Hierarchy is explicit in the structure of the tree

8

Recursion on Trees

- Recursive methods can be written to operate on trees in an obvious way
- Base case
 - empty tree
 - leaf node
- Recursive case
 - solve problem on left and right subtrees
 - put solutions together to get solution for full tree

9

Searching in a Binary Tree

```
public static boolean treeSearch(Object x,
    TreeCell node) {
    if (node == null) return false;
    if (node.datum.equals(x)) return true;
    return treeSearch(x, node.left) ||
        treeSearch(x, node.right);
}
```

- Analog of linear search in lists: given tree and an object, find out if object is stored in tree
- Easy to write recursively, harder to write iteratively

10

Binary Search Tree (BST)

- If the tree data are *ordered* – in any subtree,
 - All *left* descendants of node come *before* node
 - All *right* descendants of node come *after* node
- This makes it *much* faster to search

```
public static boolean treeSearch (Object x, TreeCell node) {
    if (node == null) return false;
    if (node.datum.equals(x)) return true;
    if (node.datum.compareTo(x) > 0)
        return treeSearch(x, node.left);
    else return treeSearch(x, node.right);
}
```

11

Building a BST

- To insert a new item
 - Pretend to look for the item
 - Put the new node in the place where you fall off the tree
- This can be done using either recursion or iteration
- Example
 - Tree uses *alphabetical order*
 - Months appear for insertion in *calendar order*

12

What Can Go Wrong?

- A BST makes searches very fast, *unless...*
 - Nodes are inserted in alphabetical order
 - In this case, we're basically building a linked list (with some extra wasted space for the `left` fields that aren't being used)
- BST works great if data arrives in random order

13

Printing Contents of BST

- Because of the ordering rules for a BST, it's easy to print the items in alphabetical order
 - Recursively print everything in the left subtree
 - Print the node
 - Recursively print everything in the right subtree

```
/**
 * Show the contents of the BST in
 * alphabetical order.
 */
public void show () {
    show(root);
    System.out.println();
}

private static void show(TreeNode node) {
    if (node == null) return;
    show(node.lchild);
    System.out.print(node.datum + " ");
    show(node.rchild);
}
```

14

Tree Traversals

- "Walking" over the whole tree is a *tree traversal*
 - This is done often enough that there are standard names
 - The previous example is an *inorder traversal*
 - Process left subtree
 - Process node
 - Process right subtree
- Note: we're using this for printing, but any kind of processing can be done
- There are other standard kinds of traversals
 - Preorder traversal**
 - Process node
 - Process left subtree
 - Process right subtree
 - Postorder traversal**
 - Process left subtree
 - Process right subtree
 - Process node
 - Level-order traversal**
 - Not recursive
 - Uses a queue

15

Some Useful Methods

```
//determine if a node is a leaf
public static boolean isLeaf(TreeCell node) {
    return (node != null) && (node.left == null)
        && (node.right == null);
}

//compute height of tree using postorder traversal
public static int height(TreeCell node) {
    if (node == null) return -1; //empty tree
    if (isLeaf(node)) return 0;
    return 1 + Math.max(height(node.left),
        height(node.right));
}

//compute number of nodes using postorder traversal
public static int nNodes(TreeCell node) {
    if (node == null) return 0;
    return 1 + nNodes(node.left) + nNodes(node.right);
}
```

16

Useful Facts about Binary Trees

- 2^d = maximum number of nodes at depth d
- If height of tree is h
 - Minimum number of nodes in tree = $h + 1$
 - Maximum number of nodes in tree = $2^0 + 2^1 + \dots + 2^h = 2^{h+1} - 1$
- Complete binary tree
 - All levels of tree down to a certain depth are completely filled

Tree with Parent Pointers

- In some applications, it is useful to have trees in which nodes can reference their parents
- Analog of doubly-linked lists

18

BSP Trees

- BSP = Binary Space Partition
- Used to render 3D images composed of polygons
- Each node **n** has one polygon **p** as data
- Left subtree of **n** contains all polygons on one side of **p**
- Right subtree of **n** contains all polygons on the other side of **p**
- Order of traversal determines occlusion!

25

Tree Summary

- A *tree* is a recursive data structure
 - Each cell has 0 or more successors (*children*)
 - Each cell except the *root* has at exactly one predecessor (*parent*)
 - All cells are reachable from the *root*
 - A cell with no children is called a *leaf*
- Special case: *binary tree*
 - Binary tree cells have a left and a right child
 - Either or both children can be null
- Trees are useful for exposing the recursive structure of natural language and computer programs
