

TREES

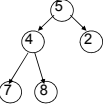

Lecture 10
CS2110 – Spring 2013

Tree Overview

- Tree: recursive data structure (similar to list)
 - Each cell may have zero or more successors (children)
 - Each cell has exactly one predecessor (parent) except the root, which has none
 - All cells are reachable from root
- Binary tree: tree in which each cell can have at most two children: a left child and a right child

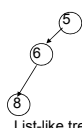

General tree

Binary tree

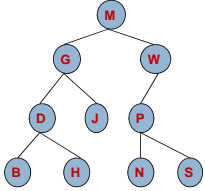

Not a tree

List-like tree

Tree Terminology

- M is the **root** of this tree
- G is the **root** of the **left subtree** of M
- B, H, J, N, and S are **leaves**
- N is the **left child** of P; S is the **right child**
- P is the **parent** of N
- M and G are **ancestors** of D
- P, N, and S are **descendants** of W
- Node J is at **depth 2** (i.e., **depth** = length of path from root = number of edges)
- Node W is at **height 2** (i.e., **height** = length of longest path to a leaf)
- A collection of several trees is called a ...?

Class for Binary Tree Cells

```

class TreeCell<T> {
    private T datum;
    private TreeCell<T> left, right;

    public TreeCell(T x) { datum = x; }
    public TreeCell(T x, TreeCell<T> lft,
                    TreeCell<T> rgt) {
        datum = x;
        left = lft;
        right = rgt;
    }
    // more methods: getDatum, setDatum,
    // getLeft, setLeft, getRight, setRight
}
    
```

Points to left subtree

Points to right subtree

... new TreeCell<String>("hello") ...

Binary versus general tree

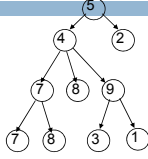

- In a binary tree each node has exactly two pointers: to the left subtree, and to the right one
 - Of course one or both could be *null*
- In a general tree a node can have any number of child nodes
 - Very useful in some situations...
 - ... one of which will be our assignments!

Class for General Tree nodes

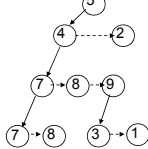

```

class GTreeCell {
    private Object datum;
    private GTreeCell left;
    private GTreeCell sibling;

    // appropriate getter and
    // setter methods
}
    
```

General tree

Tree represented using GTreeCell

- Parent node points directly only to its leftmost child
- Leftmost child has pointer to next sibling, which points to next sibling, etc.

Applications of Trees

- Most languages (natural and computer) have a recursive, hierarchical structure
- This structure is *implicit* in ordinary textual representation
- Recursive structure can be made *explicit* by representing sentences in the language as trees: **Abstract Syntax Trees (ASTs)**
- ASTs are easier to optimize, generate code from, etc. than textual representation
- A **parser** converts textual representations to AST

Example

<ul style="list-style-type: none"> □ Expression grammar: <ul style="list-style-type: none"> □ $E \rightarrow \text{integer}$ □ $E \rightarrow (E + E)$ □ In textual representation <ul style="list-style-type: none"> □ Parentheses show hierarchical structure □ In tree representation <ul style="list-style-type: none"> □ Hierarchy is explicit in the structure of the tree 	<table border="0"> <tr> <td>Text</td> <td>AST Representation</td> </tr> <tr> <td>-34</td> <td></td> </tr> <tr> <td>(2 + 3)</td> <td></td> </tr> <tr> <td>((2+3) + (5+7))</td> <td></td> </tr> </table>	Text	AST Representation	-34		(2 + 3)		((2+3) + (5+7))	
Text	AST Representation								
-34									
(2 + 3)									
((2+3) + (5+7))									

Recursion on Trees

- Recursive methods can be written to operate on trees in an obvious way
- Base case
 - empty tree
 - leaf node
- Recursive case
 - solve problem on left and right subtrees
 - put solutions together to get solution for full tree

Searching in a Binary Tree

```

public static boolean treeSearch(Object x,
                                TreeCell node) {
    if (node == null) return false;
    if (node.datum.equals(x)) return true;
    return treeSearch(x, node.left) ||
           treeSearch(x, node.right);
}
    
```

- Analog of linear search in lists: given tree and an object, find out if object is stored in tree
- Easy to write recursively, harder to write iteratively

Binary Search Tree (BST)

- If the tree data are ordered – in any subtree,
 - All left descendents of node come before node
 - All right descendents of node come after node
- This makes it *much* faster to search

```

public static boolean treeSearch (Object x, TreeCell node) {
    if (node == null) return false;
    if (node.datum.equals(x)) return true;
    if (node.datum.compareTo(x) > 0)
        return treeSearch(x, node.left);
    else return treeSearch(x, node.right);
}
    
```

Building a BST

- To insert a new item
 - Pretend to look for the item
 - Put the new node in the place where you fall off the tree
- This can be done using either recursion or iteration
- Example
 - Tree uses alphabetical order
 - Months appear for insertion in calendar order

What Can Go Wrong?

- A BST makes searches very fast, *unless...*
 - Nodes are inserted in alphabetical order
 - In this case, we're basically building a linked list (with some extra wasted space for the **Left** fields that aren't being used)
- BST works great if data arrives in random order

Printing Contents of BST

Because of the ordering rules for a BST, it's easy to print the items in alphabetical order

- Recursively print everything in the left subtree
- Print the node
- Recursively print everything in the right subtree

```

/**
 * Show the contents of the BST in
 * alphabetical order.
 */
public void show () {
    show(root);
    System.out.println();
}

private static void show(TreeNode node) {
    if (node == null) return;
    show(node.lchild);
    System.out.print(node.datum + " ");
    show(node.rchild);
}
    
```

Tree Traversals

- "Walking" over the whole tree is a tree traversal
 - This is done often enough that there are standard names
 - The previous example is an **inorder traversal**
 - Process left subtree
 - Process node
 - Process right subtree
- Note: we're using this for printing, but any kind of processing can be done
- There are other standard kinds of traversals
 - Preorder traversal**
 - Process node
 - Process left subtree
 - Process right subtree
 - Postorder traversal**
 - Process left subtree
 - Process right subtree
 - Process node
 - Level-order traversal**
 - Not recursive
 - Uses a queue

Some Useful Methods

```

//determine if a node is a leaf
public static boolean isLeaf(TreeCell node) {
    return (node != null) && (node.left == null)
        && (node.right == null);
}

//compute height of tree using postorder traversal
public static int height(TreeCell node) {
    if (node == null) return -1; //empty tree
    if (isLeaf(node)) return 0;
    return 1 + Math.max(height(node.left),
        height(node.right));
}

//compute number of nodes using postorder traversal
public static int nNodes(TreeCell node) {
    if (node == null) return 0;
    return 1 + nNodes(node.left) + nNodes(node.right);
}
    
```

Useful Facts about Binary Trees

- 2^d = maximum number of nodes at depth d
- If height of tree is h
 - Minimum number of nodes in tree = $h + 1$
 - Maximum number of nodes in tree = $2^0 + 2^1 + \dots + 2^h = 2^{h+1} - 1$
- Complete binary tree
 - All levels of tree down to a certain depth are completely filled

Tree with Parent Pointers

- In some applications, it is useful to have trees in which nodes can reference their parents
- Analog of doubly-linked lists

BSP Trees

25

- BSP = Binary Space Partition
- Used to render 3D images composed of polygons
- Each node **n** has one polygon **p** as data
- Left subtree of **n** contains all polygons on one side of **p**
- Right subtree of **n** contains all polygons on the other side of **p**
- Order of traversal determines occlusion!

Tree Summary

26

- A *tree* is a recursive data structure
 - Each cell has 0 or more successors (*children*)
 - Each cell except the *root* has at exactly one predecessor (*parent*)
 - All cells are reachable from the *root*
 - A cell with no children is called a *leaf*
- Special case: *binary tree*
 - Binary tree cells have a left and a right child
 - Either or both children can be null
- Trees are useful for exposing the recursive structure of natural language and computer programs
