

Triangle meshes

CS 465 Lecture 13

Notation

- $n_T = \#tris$; $n_V = \#verts$; $n_E = \#edges$
- Euler: $n_V - n_E + n_T = 2$ for a simple closed surface
 - and in general sums to small integer
 - argument for implication that $n_T:n_E:n_V$ is about 2:3:1

[Foley et al.]

Validity of triangle meshes

- in many cases we care about the mesh being able to bound a region of space nicely
- in other cases we want triangle meshes to fulfill assumptions of algorithms that will operate on them (and may fail on malformed input)
- two completely separate issues:
 - topology: how the triangles are connected (ignoring the positions entirely)
 - geometry: where the triangles are in 3D space

Topology/geometry examples

- same geometry, different mesh topology:

- same mesh topology, different geometry:

Topological validity

- strongest property, and most simple: be a manifold
 - this means that no points should be "special"
 - interior points are fine
 - edge points: each edge should have exactly 2 triangles
 - vertex points: each vertex should have one loop of triangles
 - not too hard to weaken this to allow boundaries

Geometric validity

- generally want non-self-intersecting surface
- hard to guarantee in general
 - because far-apart parts of mesh might intersect

Representation of triangle meshes

- Compactness
- Efficiency for rendering
 - enumerate all triangles as triples of 3D points
- Efficiency of queries
 - all vertices of a triangle
 - all triangles around a vertex
 - neighboring triangles of a triangle
 - (need depends on application)
 - finding triangle strips
 - computing subdivision surfaces
 - mesh editing

Representations for triangle meshes

- Separate triangles
- Indexed triangle set
 - shared vertices
- Triangle strips and triangle fans
 - compression schemes for transmission to hardware
- Triangle-neighbor data structure
 - supports adjacency queries
- Winged-edge data structure
 - supports general polygon meshes

Separate triangles

Separate triangles

- array of triples of points
 - $\text{float}[n_T][3][3]$: about 72 bytes per vertex
 - 2 triangles per vertex (on average)
 - 3 vertices per triangle
 - 3 coordinates per vertex
 - 4 bytes per coordinate (float)
- various problems
 - wastes space (each vertex stored 6 times)
 - cracks due to roundoff
 - difficulty of finding neighbors at all

Indexed triangle set

- Store each vertex once
- Each triangle points to its three vertices

Indexed triangle set

- Store each vertex once
- Each triangle points to its three vertices

Indexed triangle set

```
verts[0] x0, y0, z0
verts[1] x1, y1, z1
         x2, y2, z2
         x3, y3, z3
         ⋮
```

```
tInd[0] 0, 2, 1
tInd[1] 0, 3, 2
        ⋮
```

Indexed triangle set

- array of vertex positions
 - $\text{float}[n_V][3]$: 12 bytes per vertex
 - (3 coordinates \times 4 bytes) per vertex
- array of triples of indices (per triangle)
 - $\text{int}[n_T][3]$: about 24 bytes per triangle
 - 2 triangles per vertex (on average)
 - (3 indices \times 4 bytes) per triangle
- total storage: 36 bytes per vertex (factor of 2 savings)
- represents topology and geometry separately
- finding neighbors is at least well defined

Triangle strips

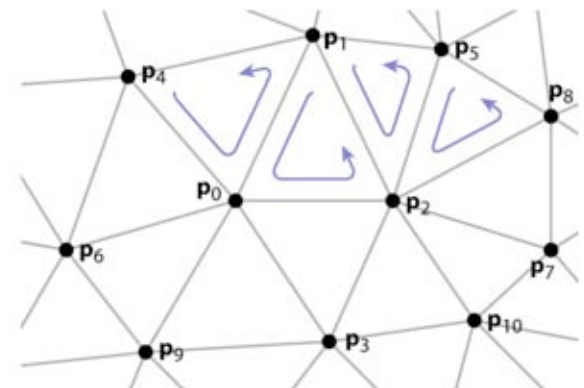

- Take advantage of the mesh property
 - each triangle is usually adjacent to the previous
 - let every vertex create a triangle by reusing the second and third vertices of the previous triangle
 - every sequence of three vertices produces a triangle (but not in the same order)
 - e. g., 0, 1, 2, 3, 4, 5, 6, 7, ... leads to (0 1 2), (2 1 3), (2 3 4), (4 3 5), (4 5 6), (6 5 7), ...
 - for long strips, this requires about one index per triangle

Triangle strips

```
verts[0] x0, y0, z0
verts[1] x1, y1, z1
         x2, y2, z2
         x3, y3, z3
         ⋮
```

```
tStrip[0] 4, 0, 1, 2, 5, 8
tStrip[1] 6, 9, 0, 3, 2, 10, 7
        ⋮
```

Triangle strips

Triangle strips

- array of vertex positions
 - $\text{float}[n_V][3]$: 12 bytes per vertex
 - (3 coordinates \times 4 bytes) per vertex
- array of index lists
 - $\text{int}[n_S][\text{variable}]$: $2 + n$ indices per strip
 - on average, $(1 + \epsilon)$ indices per triangle (assuming long strips)
 - 2 triangles per vertex (on average)
 - about 4 bytes per triangle (on average)
- total is 20 bytes per vertex (limiting best case)
 - factor of 3.6 over separate triangles; 1.8 over indexed mesh

Triangle fans

- Same idea as triangle strips, but keep oldest rather than newest
 - every sequence of three vertices produces a triangle
 - e. g., 0, 1, 2, 3, 4, 5, ... leads to $(0\ 1\ 2)$, $(0\ 2\ 3)$, $(0\ 3\ 4)$, $(0\ 3\ 5)$, ...
 - for long fans, this requires about one index per triangle
- Memory considerations exactly the same as triangle strip

Triangle neighbor structure

- Extension to indexed triangle set
- Triangle points to its three neighboring triangles
- Vertex points to a single neighboring triangle
- Can now enumerate triangles around a vertex

Triangle neighbor structure

- Extension to indexed triangle set
- Triangle points to its three neighboring triangles
- Vertex points to a single neighboring triangle
- Can now enumerate triangles around a vertex

Triangle neighbor structure

- Extension to indexed triangle set
- Triangle points to its three neighboring triangles
- Vertex points to a single neighboring triangle
- Can now enumerate triangles around a vertex

Triangle neighbor structure

vTri[0]	0	tNbr[0]	1, 6, 7

Triangle neighbor structure

- indexed mesh was 36 bytes per vertex
- add an array of triples of indices (per triangle)
 - int[n_T][3]: about 24 bytes per vertex
 - 2 triangles per vertex (on average)
 - (3 indices x 4 bytes) per triangle
- total storage: 60 bytes per vertex
 - still not as much as separate triangles

Winged-edge mesh

- Edge-centric rather than face-centric
 - therefore also works for polygon meshes
- Each (oriented) edge points to:
 - left and right forward edges
 - left and right backward edges
 - front and back vertices
 - left and right faces
- Each face or vertex points to one edge

Winged-edge mesh

- Edge-centric rather than face-centric
 - therefore also works for polygon meshes
- Each (oriented) edge points to:
 - left and right forward edges
 - left and right backward edges
 - front and back vertices
 - left and right faces
- Each face or vertex points to one edge

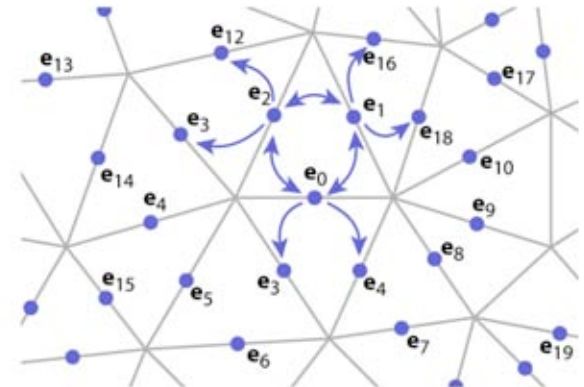

Winged-edge mesh

- Edge-centric rather than face-centric
 - therefore also works for polygon meshes
- Each (oriented) edge points to:
 - left and right forward edges
 - left and right backward edges
 - front and back vertices
 - left and right faces
- Each face or vertex points to one edge

Winged-edge structure

	hl	hr	tl	tr
edge[0]	1	4	2	3
edge[1]	18	0	16	2
edge[2]	12	1	3	0
	⋮			

Winged-edge structure

- array of vertex positions: 12 bytes/vert
- array of 8-tuples of indices (per edge)
 - head/tail left/right edges + head/tail verts + left/right tris
 - $\text{int}[n_E][8]$: about 96 bytes per vertex
 - 3 edges per vertex (on average)
 - (8 indices x 4 bytes) per triangle
- total storage: 108 bytes per vertex
 - so this is more complex than neighbor pointers
 - but it is cleaner and generalizes to polygon meshes
