

Using Color Objects in A3

- New classes in `colormodel`
 - RGB, CMYK, and HSV
- Each has its own attributes
 - RGB**: red, blue, green
 - CMYK**: cyan, magenta, yellow, black
 - HSV**: hue, saturation, value
- Attributes have *invariants*
 - Limits the attribute values
 - Example: red is int in 0..255
 - Get an error if you violate

c	id1
r	128

id1	
RGB	
red	128
green	0
blue	0

```

>>> import colormodel
>>> c = colormodel.RGB(128,0,0)
>>> r = c.red
>>> c.red = 500 # out of range
AssertionError: 500 outside [0,255]
    
```

Errors and the Call Stack

Crashes produce the call stack:

```

# error.py
def function_1(x,y):
    return function_2(x,y)
def function_2(x,y):
    return function_3(x,y)
def function_3(x,y):
    return x/y # crash here
if __name__ == '__main__':
    print function_1(1,0)
    
```

```

Traceback (most recent call last):
  File "error.py", line 20, in <module>
    print function_1(1,0)
  File "error.py", line 8, in function_1
    return function_2(x,y)
  File "error.py", line 12, in function_2
    return function_3(x,y)
  File "error.py", line 16, in function_3
    return x/y
    
```

Make sure you can see line numbers in Komodo. Preferences → Editor

Errors and the Call Stack

Crashes produce the call stack:

```

# error.py
def function_2(x,y):
    return function_3(x,y)
def function_3(x,y):
    return x/y # crash here
    
```

```

Traceback (most recent call last):
  File "error.py", line 20, in <module>
    print function_1(1,0)
  File "error.py", line 8, in function_1
    return function_2(x,y)
  File "error.py", line 12, in function_2
    return function_3(x,y)
  File "error.py", line 16, in function_3
    return x/y
    
```

Script code. Global space

Where error occurred (or where was found)

Make sure you can see line numbers in Komodo. Preferences → Editor

Assert Statements

```

assert <boolean> # Creates error if <boolean> false
assert <boolean>, <string> # As above, but displays <String>
    
```

- Way to force an error
 - Why would you do this?
- Enforce preconditions!
 - Put precondition as `assert`.
 - If violate precondition, the program crashes
- Provided code in A3 uses asserts heavily

```

def exchange(amt, from_c, to_c):
    """Returns: amt from exchange
    Precondition: amt is a float..."""
    assert type(amt) == float
    ...
    
```

Will do yourself in A4.

Example: Anglicizing an Integer

```

def anglicize(n):
    """Returns: the anglicization of int n.
    Precondition: n an int, 0 < n < 1,000,000"""
    assert type(n) == int, str(n)+' is not an int'
    assert 0 < n and n < 1000000, str(n)+' is out of range'
    # Implement method here...
    
```

Check (part of) the precondition

Error message when violated

Enforcing Preconditions is Tricky!

```

def lookup_netid(nid):
    """Returns: name of student with netid nid.
    Precondition: nid is a string, which consists of
    2 or 3 letters and a number"""
    assert type(nid) == str, str(nid) + ' is not a string'
    assert nid.isalphanum(), nid+' is not just letters/digits'
    
```

Returns True if s contains only letters, numbers.

Does this catch all violations?

Using Function to Enforce Preconditions

```
def exchange(curr_from, curr_to, amt_from):
    """Returns: amount of curr_to received.
    Precondition: curr_from is a valid currency code
    Precondition: curr_to is a valid currency code
    Precondition: amt_from is a float"""
    assert ?????, str(curr_from) + ' not valid'
    assert ?????, str(curr_to) + ' not valid'
    assert type(amt_from)==float, str(amt_from) + ' not a float'
```

Recovering from Errors

- try-except blocks allow us to recover from errors
 - Do the code that is in the try-block
 - Once an error occurs, jump to the catch

Example:

```
try:
    input = raw_input() # get number from user
    x = float(input) # convert string to float
    print 'The next number is '+str(x+1)
except:
    print 'Hey! That is not a number!'
```

might have an error (pointing to float conversion)

executes if error happens (pointing to except block)

Try-Except is Very Versatile

```
def isfloat(s):
    """Returns: True if string
    s represents a float"""
    try:
        x = float(s)
        return True
    except:
        return False
```

Conversion to a float might fail

If attempt succeeds, string s is a float

Otherwise, it is not

Try-Except and the Call Stack

```
# recover.py
def function_1(x,y):
    try:
        return function_2(x,y)
    except:
        return float('inf')
def function_2(x,y):
    return function_3(x,y)
def function_3(x,y):
    return x/y # crash here
```

- Error “pops” frames off stack
 - Starts from the stack bottom
 - Continues until it sees that current line is in a try-block
 - Jumps to except, and then proceeds as if no error

Tracing Control Flow

```
def first(x):
    print 'Starting first.'
    try:
        second(x)
    except:
        print 'Caught at first'
    print 'Ending first'

def second(x):
    print 'Starting second.'
    try:
        third(x)
    except:
        print 'Caught at second'
    print 'Ending second'

def third(x):
    print 'Starting third.'
    assert x < 1
    print 'Ending third.'
```

What is the output of first(2)?

Tracing Control Flow

```
def first(x):
    print 'Starting first.'
    try:
        second(x)
    except:
        print 'Caught at first'
    print 'Ending first'

def second(x):
    print 'Starting second.'
    try:
        third(x)
    except:
        print 'Caught at second'
    print 'Ending second'

def third(x):
    print 'Starting third.'
    assert x < 1
    print 'Ending third.'
```

What is the output of first(0)?
