

Lecture 15

# **Recursion**

# Announcements for Today

---

## Prelim 1

---

- Tonight at 7:30-9pm
  - **A-J** (Uris G01)
  - **K-Z** (Statler Auditorium)
- Graded by noon on Sun
  - Scores will be in CMS
  - In time for drop date
- Make-ups were e-mailed
  - If not, e-mail Jessica NOW

## Other Announcements

---

- Reading: 5.8 – 5.10
- Assignment 3 now graded
  - **Mean** 94, **Median** 99
  - **Time**: 7 hrs, **StdDev**: 3 hrs
  - Unchanged from last year
- Assignment 4 posted Friday
  - Parts 1-3: Can do already
  - Part 4: material from today
  - Due two weeks from today

# Recursion

---

- **Recursive Definition:**

A definition that is defined in terms of itself

- **Recursive Function:**

A function that calls itself (directly or indirectly)

- **Recursion:** If you understand the definition, stop;  
otherwise, see Recursion

- **Infinite Recursion:** See Infinite Recursion

# A Mathematical Example: Factorial

---

- Non-recursive definition:

$$\begin{aligned}n! &= n \times n-1 \times \dots \times 2 \times 1 \\ &= n (n-1 \times \dots \times 2 \times 1)\end{aligned}$$

- Recursive definition:

$$n! = n (n-1)! \quad \text{for } n \geq 0 \quad \text{Recursive case}$$

$$0! = 1 \quad \text{Base case}$$

What happens if there is no base case?

# Factorial as a Recursive Function

```
def factorial(n):
```

```
    """Returns: factorial of n.
```

```
    Pre: n ≥ 0 an int"""
```

```
    if n == 0:
```

```
        | return 1
```

```
    return n*factorial(n-1)
```

- $n! = n (n-1)!$

- $0! = 1$

**Base case(s)**

**Recursive case**

What happens if there is no base case?

# Example: Fibonacci Sequence

---

- Sequence of numbers: 1, 1, 2, 3, 5, 8, 13, ...

$$a_0 \quad a_1 \quad a_2 \quad a_3 \quad a_4 \quad a_5 \quad a_6$$

- Get the next number by adding previous two
- What is  $a_8$ ?

A:  $a_8 = 21$

B:  $a_8 = 29$

C:  $a_8 = 34$

D: None of these.

# Example: Fibonacci Sequence

---

- Sequence of numbers: 1, 1, 2, 3, 5, 8, 13, ...

$a_0$   $a_1$   $a_2$   $a_3$   $a_4$   $a_5$   $a_6$

- Get the next number by adding previous two
- What is  $a_8$ ?

A:  $a_8 = 21$

B:  $a_8 = 29$

C:  $a_8 = 34$  **correct**

D: None of these.

# Example: Fibonacci Sequence

---

- Sequence of numbers: 1, 1, 2, 3, 5, 8, 13, ...

$$a_0 \quad a_1 \quad a_2 \quad a_3 \quad a_4 \quad a_5 \quad a_6$$

- Get the next number by adding previous two
  - What is  $a_8$ ?
- Recursive definition:
    - $a_n = a_{n-1} + a_{n-2}$       **Recursive Case**
    - $a_0 = 1$       **Base Case**
    - $a_1 = 1$       **(another) Base Case**

Why did we need two base cases this time?

# Fibonacci as a Recursive Function

---

```
def fibonacci(n):
```

```
    """Returns: Fibonacci no.  $a_n$ 
```

```
    Precondition:  $n \geq 0$  an int"""
```

```
    if n <= 1:
```

```
        | return 1
```

**Base case(s)**

```
    return (fibonacci(n-1)+  
            fibonacci(n-2))
```

**Recursive case**

Note difference with base case conditional.

# Fibonacci as a Recursive Function

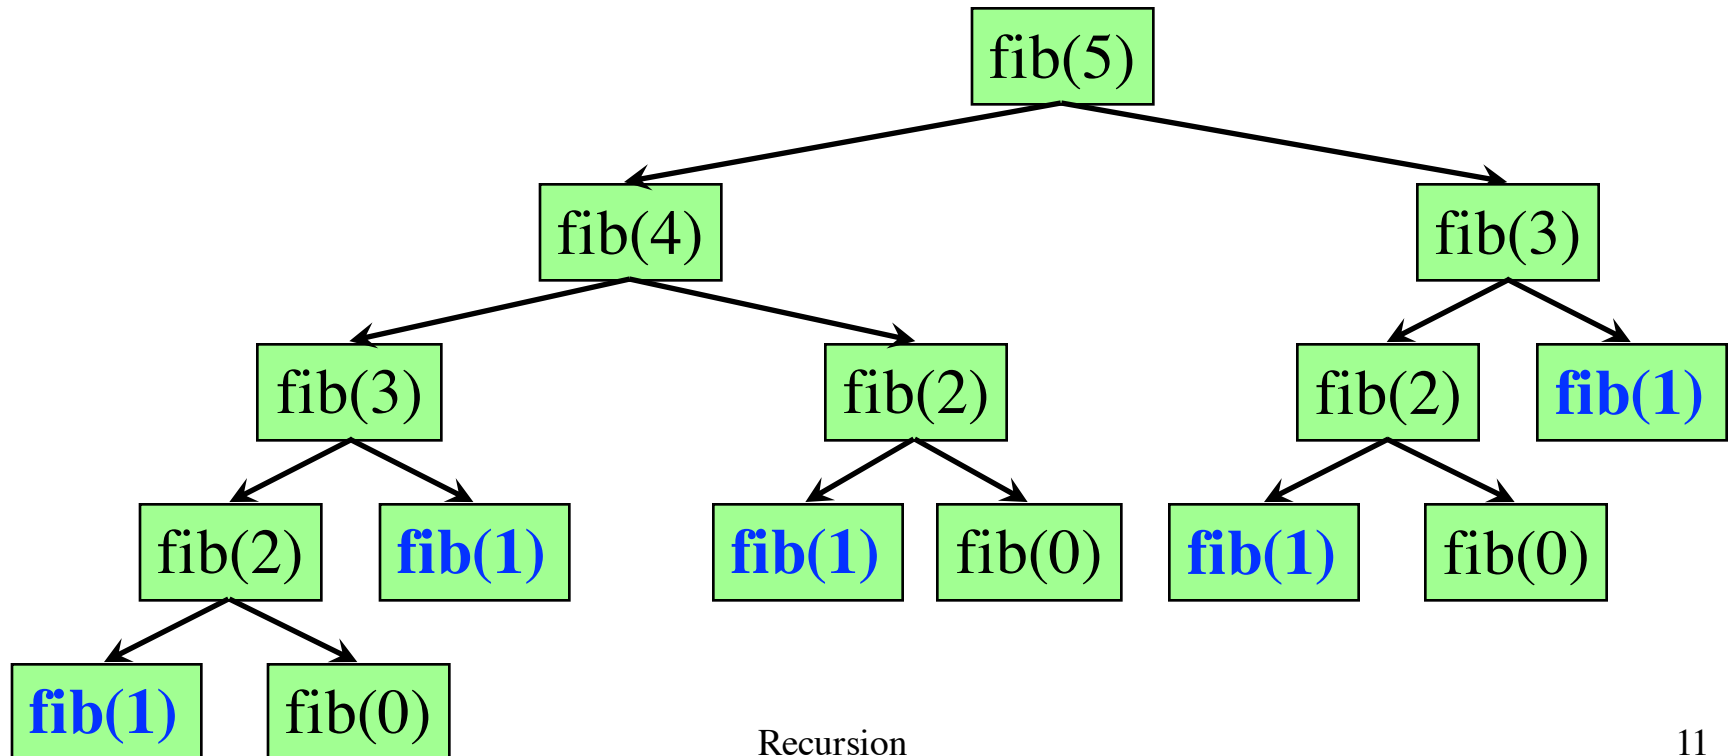

```
def fibonacci(n):  
    """Returns: Fibonacci no.  $a_n$   
    Precondition:  $n \geq 0$  an int"""  
    if n <= 1:  
        return 1  
  
    return (fibonacci(n-1)+  
            fibonacci(n-2))
```

- Function that calls itself
  - Each call is new frame
  - Frames require memory
  - $\infty$  calls =  $\infty$  memory

# Fibonacci: # of Frames vs. # of Calls

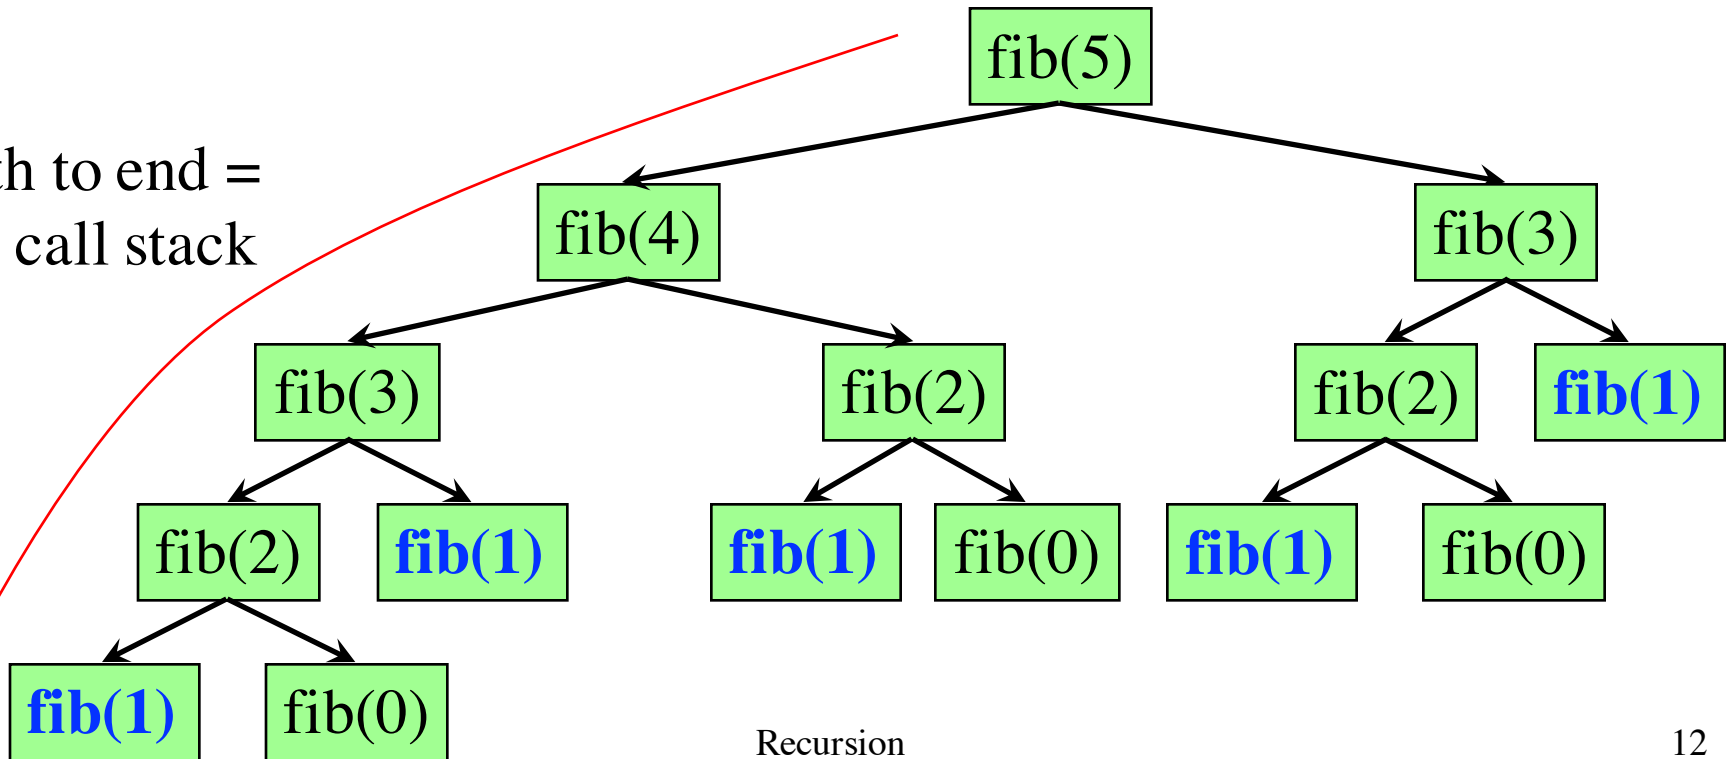

- Fibonacci is very inefficient.
  - $\text{fib}(n)$  has a stack that is always  $\leq n$
  - But  $\text{fib}(n)$  makes a lot of **redundant calls**

# Fibonacci: # of Frames vs. # of Calls

- Fibonacci is very inefficient.
  - $\text{fib}(n)$  has a stack that is always  $\leq n$
  - But  $\text{fib}(n)$  makes a lot of **redundant calls**

Path to end =  
the call stack

# Two Major Issues with Recursion

---

- **How are recursive calls executed?**
  - We saw this with the Fibonacci example
  - Use the call frame model of execution
- **How do we understand a recursive function (and how do we create one)?**
  - You cannot trace the program flow to understand what a recursive function does – too complicated
  - You need to rely on the **function specification**

# How to Think About Recursive Functions

---

- 1. Have a precise function specification.**
- 2. Base case(s):**
  - When the parameter values are as small as possible
  - When the answer is determined with little calculation.
- 3. Recursive case(s):**
  - Recursive calls are used.
  - Verify recursive cases with the specification
- 4. Termination:**
  - Arguments of calls must somehow get “smaller”
  - Each recursive call must get closer to a base case

# Understanding the String Example

```
def num_es(s):  
    """Returns: # of 'e's in s"""  
    # s is empty  
    if s == "":  
        return 0  
  
    # s has at least one 'e'  
    if s[0] == 'e':  
        return 1+num_es(s[1:])  
  
    return num_es(s[1:])
```

**Base case**

**Recursive case**

- Break problem into parts

number of e's in s =  
    number of e's in s[0]  
    + number of e's in s[1:]

- Solve small part directly

number of e's in s =  
    number of e's in s[1:]  
    (+1 if s[0] is an 'e')  
    (+0 if s[0] not an 'e')

# Understanding the String Example

- **Step 1:** Have a precise specification

```
def num_es(s):
```

```
    """Returns: # of 'e's in s"""
```

```
    # s is empty
```

```
    if s == ":
```

```
        | return 0
```

**Base case**

```
    # return # of 'e's in s[0]+# of 'e's in s[1:]
```

```
    if s[0] == 'e':
```

```
        | return 1+num_es(s[1:])
```

**Recursive case**

```
    return num_es(s[1:])
```

“Write” your return statement using the **specification**

- **Step 2:** Check the base case

- When s is the empty string, 0 is (correctly) returned.

# Understanding the String Example

- **Step 3:** Recursive calls make progress toward termination

```
def num_es(s): ← parameter s  
    """Returns: # of 'e's in s"""  
    # s is empty  
    if s == "":  
        | return 0  
  
    # return # of 'e's in s[0]+# of 'e's in s[1:]  
    if s[0] == 'e':  
        | return 1+num_es(s[1:]) argument s[1:]  
  
    return num_es(s[1:])
```

argument `s[1:]` is smaller than parameter `s`, so there is progress toward reaching base case 0

- **Step 4:** Check the recursive case
  - Does it match the specification?

# Exercise: Remove Blanks from a String

---

1. Have a precise specification

```
def deblank(s):
```

```
    |   """Returns: s but with its blanks removed"""
```

2. **Base Case:** the smallest String s is "".

```
if s == ":
```

```
    |   return s
```

3. **Other Cases:** String s has at least 1 character.

```
return (s[0] with blanks removed) + (s[1:] with blanks removed)
```

# Exercise: Remove Blanks from a String

---

1. Have a precise specification

```
def deblank(s):
```

```
    """Returns: s but with its blanks removed"""
```

2. **Base Case:** the smallest String s is "".

```
if s == ":
```

```
    return s
```

3. **Other Cases:** String s has at least 1 character.

```
return (s[0] with blanks removed) + (s[1:] with blanks removed)
```

```
(" if s[0] == ' ' else s[0])
```

# What the Recursion Does

# Exercise: Remove Blanks from a String

---

```
def deblank(s):  
    """Returns: s with blanks removed"""  
    if s == "":  
        | return s  
  
    # s is not empty  
    if s[0] is a blank:  
        | return s[1:] with blanks removed  
  
    # s not empty and s[0] not blank  
    return (s[0] +  
            s[1:] with blanks removed)
```

- Sometimes easier to break up the recursive case
  - Particularly on small part
  - Write recursive case as a sequence of if-statements
- Write code in *pseudocode*
  - Mixture of English and code
  - Similar to top-down design
- Stuff in **red** looks like the function specification!
  - But on a smaller string
  - Replace with deblank(s[1:])

# Exercise: Remove Blanks from a String

```
def deblank(s):  
    """Returns: s with blanks removed"""  
    if s == "":  
        | return s  
  
    # s is not empty  
    if s[0] in string.whitespace:  
        | return deblank(s[1:])  
  
    # s not empty and s[0] not blank  
    return (s[0] +  
            deblank(s[1:]))
```

- Check the four points:
  1. Precise specification?
  2. **Base case**: correct?
  3. Progress towards termination?
  4. **Recursive case**: correct?

Module `string` has special constants to simplify detection of whitespace and other characters.

# Example: Reversing a String

- **Precise Specification:**
  - Returns: reverse of s
- Solving with recursion
  - Suppose we can reverse a smaller string (e.g. less one character)
  - Can we use that solution to reverse whole string?
- Often easy to understand first without Python
  - Then sit down and code

# Example: Reversing a String

- **Precise Specification:**
  - Returns: reverse of s
- Solving with recursion
  - Suppose we can reverse a smaller string (e.g. less one character)
  - Can we use that solution to reverse whole string?
- Often easy to understand first without Python
  - Then sit down and code

# Example: Reversing a String

- **Precise Specification:**
  - Returns: reverse of s
- Solving with recursion
  - Suppose we can reverse a smaller string (e.g. less one character)
  - Can we use that solution to reverse whole string?
- Often easy to understand first without Python
  - Then sit down and code

H	e	l	l	o	!
---	---	---	---	---	---

!	o	l	l	e	H
---	---	---	---	---	---

H	e	l	l	o	!
---	---	---	---	---	---

!	o	l	l	e
---	---	---	---	---

# Example: Reversing a String

- **Precise Specification:**
  - Returns: reverse of s
- Solving with recursion

---	---	---	---	---	---

# Example: Reversing a String

```
def reverse(s):
```

```
    """Returns: reverse of s
```

```
    Precondition: s a string"""
```

```
    # s is empty
```

```
    if s == ":
```

```
        | return s
```

```
    # s has at least one char
```

```
    # (reverse of s[1:])+s[0]
```

```
    return reverse(s[1:])+s[0]
```

- ✓ 1. Precise specification?
- ✓ 2. Base case: correct?
- ✓ 3. Recursive case:  
progress to termination?
- ✓ 4. Recursive case: correct?

# **Next Time: Recursion vs. For-Loops**
