Things to Do Before Next Class

Read Textbook

- Chapter 1 (browse)
- Chapter 2 (in detail)
- Chapter 3.1 – 3.4

Lab 1

- Go to your registered section
- Complete lab handout
- Have ***one week*** to complete
  - Show to TA by end of lab, or:
  - Show in consulting hours up to the day *before* your lab, or:
  - Show to TA ***within first 10 minutes*** of next week's lab

Helping You Succeed in this Class

- **Consultants.** ACCEL Lab Green Room
  - Daily office hours (see website) with consultants
  - Very useful when working on assignments
- **AEW Workshops**. Additional discussion course
  - Runs parallel to this class – completely optional
  - See website; talk to advisors in Olin 167.
- **Piazza.** Online forum to ask and answer questions
- **Office Hours.** Talk to the professors!

Type: Set of values and the operations on them

- Type **int**:
  - **Values**: integers
  - **Ops**: +, –, *, /, %, **
- Type **float**:
  - **Values**: real numbers
  - **Ops**: +, –, *, /, **
- Type **bool**:
  - **Values**: **True** and **False**
  - **Ops**: not, and, or

- Type **str**:
  - **Values**: string literals
    - Double quotes: "abc"
    - Single quotes: 'abc'
  - **Ops**: + (concatenation)

Will see more types in a few weeks

Operator Precedence

- What is the difference between the following?
  - 2*(1+3) **add, then multiply**
  - 2*1 + 3 **multiply, then add**
- Operations are performed in a set order
  - Parentheses make the order explicit
  - What happens when there are no parentheses?
- **Operator Precedence**: The *fixed* order Python processes operators in *absence* of parentheses

Precedence of Python Operators

- **Exponentiation**: **
- **Unary operators**: + –
- **Binary arithmetic**: * / %
- **Binary arithmetic**: + –
- **Comparisons**: < > <= >=
- **Equality relations**: == !=
- **Logical not**
- **Logical and**
- **Logical or**

- Precedence goes downwards
  - Parentheses highest
  - Logical ops lowest
- Same line = same precedence
  - Read “ties” left to right
  - Example: 1/2*3 is (1/2)*3

- Section 2.7 in your text
- See website for more info
- Was major portion of Lab 1

Expressions vs Statements

Expression

- **Represents** something
  - Python *evaluates it*
  - End result is a value
- Examples:
  - 2.3 (Value)
  - (3+5)/4 (Complex Expression)

Statement

- **Does** something
  - Python *executes it*
  - Need not result in a value
- Examples:
  - print “Hello”
  - import sys

Will see later this is not a clear cut separation

Variables (Section 2.1)

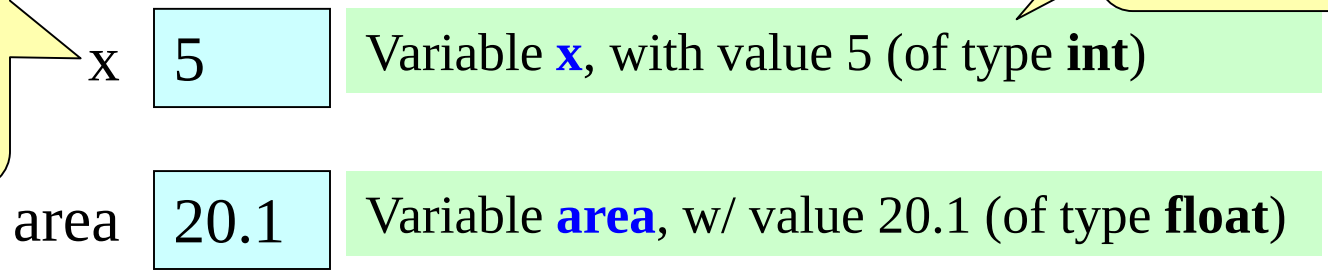
- A **variable**
  - is a **named** memory location (**box**)
  - contains a **value** (in the box)
  - can be used in expressions

The value in the box is then used in evaluating the expression.

- Examples:

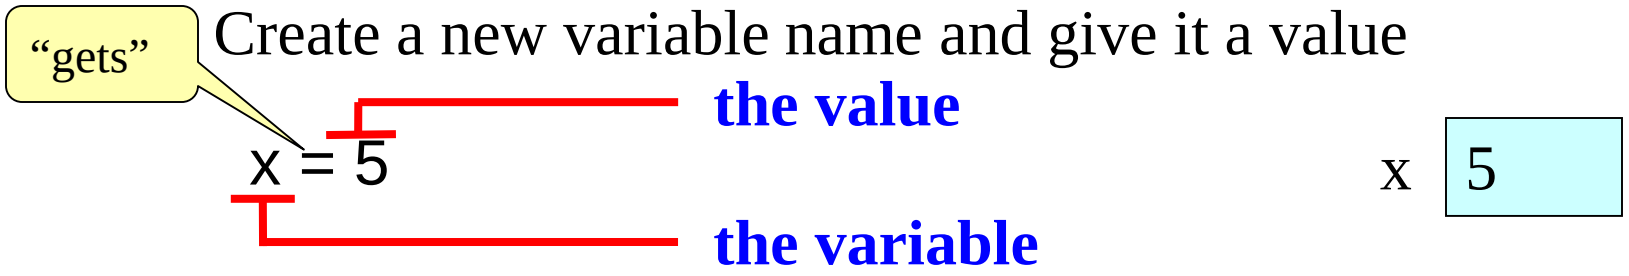
Variable names must start with a letter (or _).

The type belongs to the *value*, not to the *variable*.

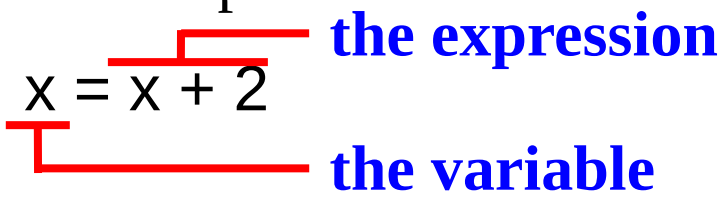


Variables and Assignment Statements

- Variables are created by **assignment statements**



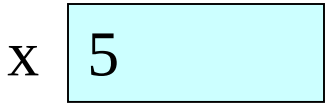
- This is a **statement**, not an **expression**
  - Tells the computer to DO something (not give a value)
  - Typing it into >>> gets no response (but it is working)
- Assignment statements can have expressions in them
  - These expressions can even have variables in them



Two steps to execute an assignment:
1. evaluate the expression on the right
2. store the result in the variable on the left

Execute the Statement: x = x + 2

- Draw variable x on piece of paper:



- Step 1: evaluate the expression x + 2
  - For x, use the value in variable x
  - Write the expression somewhere on your paper
- Step 2: Store the value of the expression in x
  - Cross off the old value in the box
  - Write the new value in the box for x
- Check to see whether you did the same thing as your neighbor, discuss it if you did something different.

Execute the Statement: x = x + 2

- The variable x

  x | 5

- The command:
  - Step 1: **Evaluate** the expression x + 2
  - Step 2: **Store** its value in x
- This is how you execute an assignment statement
  - Performing it is called **executing the command**
  - Command requires both **evaluate** AND **store** to be correct
  - Important *mental model* for understanding Python

Dynamic Typing

- Python is a **dynamically typed language**
  - Variables can hold values of any type
  - Variables can hold different types at different times
  - Use type(x) to find out the type of the value in x
  - Use names of types for conversion, comparison

```
type(x) == int
x = float(x)
type(x) ==
float
```

- The following is acceptable in Python:

```
>>> x = 1        ← x contains an int value
>>> x = x / 2.0  ← x now contains a float value
```

- Alternative is a **statically typed language** (e.g. Java)
  - Each variable restricted to values of just one type

Dynamic Typing

- Often want to track the type in a variable
  - What is the result of evaluating x / y?
  - Depends on whether x, y are **int** or **float** values
- Use expression type(<expression>) to get type
  - type(2) evaluates to <type 'int'>
  - type(x) evaluates to type of contents of x
- Can use in a boolean expression to test type
  - type('abc') == str evaluates to **True**
