

CS/ENGRD 2110

SPRING 2014

Lecture 6: Casting; function equals
<http://courses.cs.cornell.edu/cs2110>

Overview ref in text and JavaSummary.pptx

2

- Quick look at arrays **slide 50-55**
- Casting among classes **C.33-C.36 (not good)** **slide 34-41**
- Static/Dynamic types (apparent/real types) **slide 34-41**
- Operator **instanceof** **slide 40**
- Function **equals** **slide 37-41**

Homework. Learn about while/ for loops in Java. Look in text.

```
while ( <bool expr> ) { ... }           // syntax
```

```
for (int k= 0; k < 200; k= k+1) { ... } // example
```

Classes we work with today

class hierarchy:

3

Work with a class **Animal** and subclasses like **Cat** and **Dog**

Put components common to animals in **Animal**
Object, partition is there but not shown

class hierarchy:

a0

age 5	Animal
Animal(String, int) isOlder(Animal)	
Cat(String, int)	Cat
getNoise() toString() getWeight()	

a1

age 6	Animal
Animal(String, int) isOlder(Animal)	
Dog(String, int)	Dog
getNoise() toString()	

Animal[] v = new Animal[3];

4

declaration of array v

Create array of 3 elements

Assign value of new-exp to v

Assign and refer to elements as usual:

```
v[0] = new Animal(...);
```

...

```
a = v[0].getAge();
```

Sometimes use horizontal picture of an array:

Which function is called?

5

Which function is called by
`v[0].toString()` ?

	0	1	2
v	a0	null	a1

Remember,
partition Object
contains
`toString()`

a0	
age 5	Animal
Animal(String, int) isOlder(Animal)	
Cat(String, int)	Cat
getNoise() toString() getWeight()	

a1	
age 6	Animal
Animal(String, int) isOlder(Animal)	
Dog(String, int)	Dog
getNoise() toString()	

Static/apparent type

6

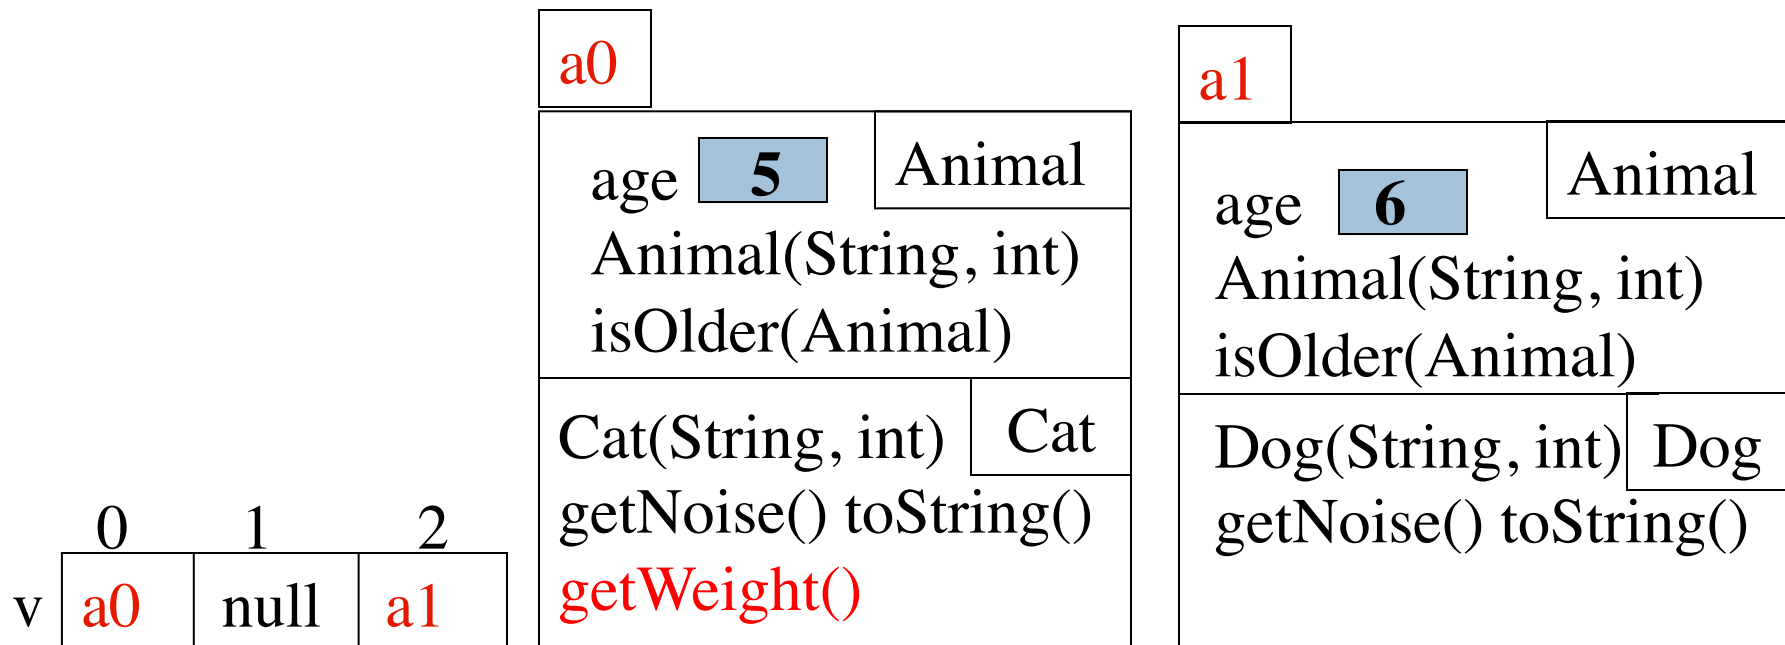

Each element $v[k]$ is of type *Animal*.
Its declared type:

static type — known at
compile-time

apparent type

Should this call be allowed?
Should program compile?

$v[0].getWeight()$

View of object from static type

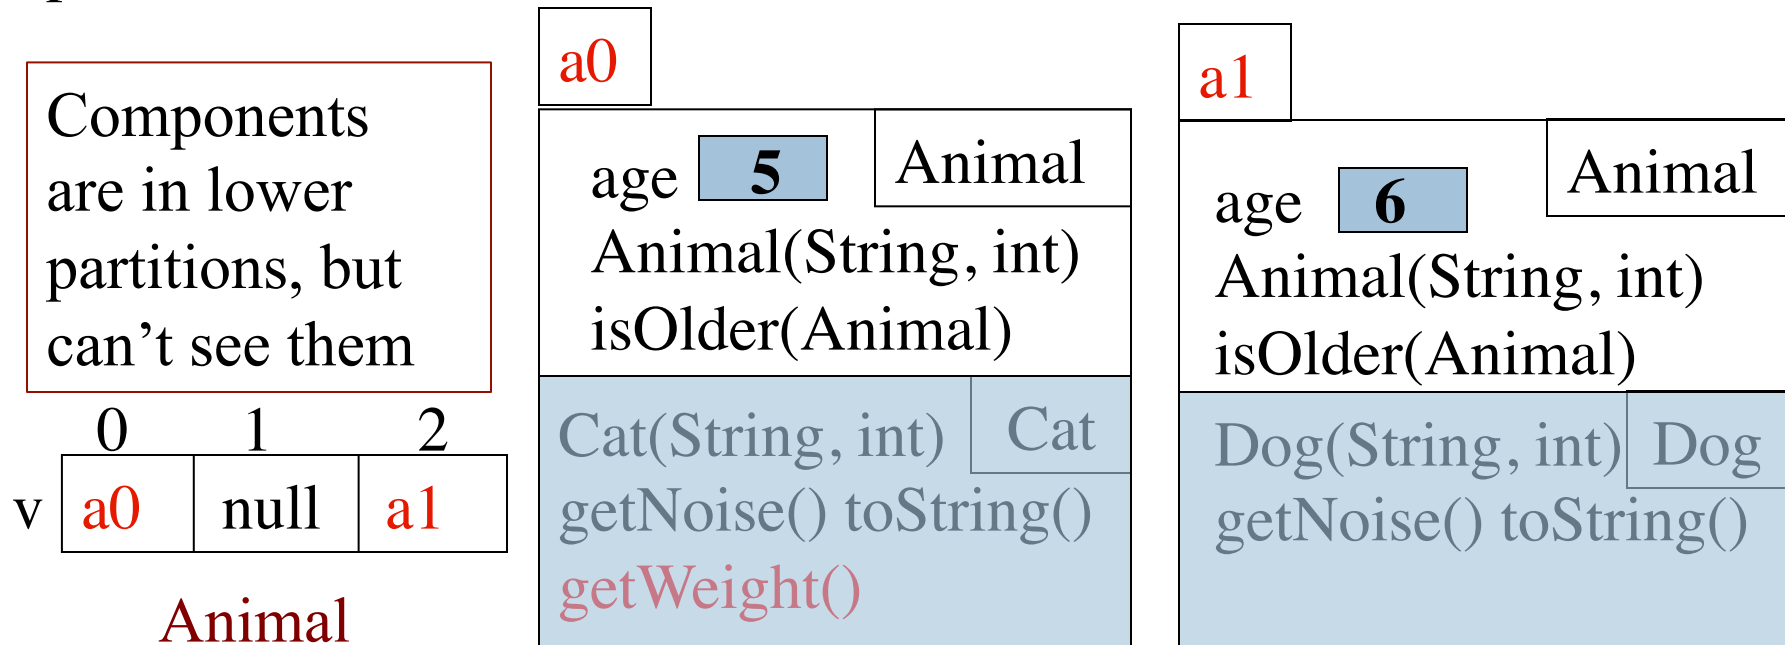

7

Each element $v[k]$ is of (static) type **Animal**.

From $v[k]$, see only what is in partition **Animal** and partitions above it.

`getWeight()` not in class **Animal** or **Object**. Calls are illegal, program does not compile:

`v[0].getWeight()` `v[k].getWeight()`

Casting up class hierarchy

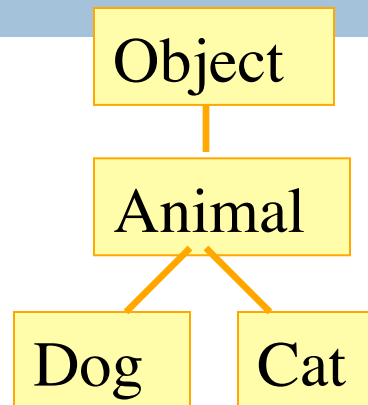

8

You know about casts like

(int) (5.0 / 7.5)

(double) 6

double d= 5; // automatic cast

a0

age	5	Animal
Animal(String, int) isOlder(Animal)		
Cat(String, int)		Cat
getNoise() toString() getWeight()		

a1

age	6	Animal
Animal(String, int) isOlder(Animal)		
Dog(String, int)		Dog
getNoise() toString()		

We now discuss casts up and down the class hierarchy.

Animal h= **new** Cat("N", 5);

Cat c= (Cat) h;

Implicit upward cast

9

```
public class Animal {  
    /** = "this Animal is older than h" */  
    public boolean isOlder(Animal h) {  
        return age > h.age;  
    }  
}
```

Call `c.isOlder(d)`

`h` is created. `a1` is cast up to class `Animal` and stored in `h`

Upward casts done automatically when needed

`a0`

age	<code>5</code>	Animal
Animal(String, int)		
isOlder(Animal)		

Cat(String, int)	Cat
getNoise() toString()	
getWeight()	

`a1`

age	<code>6</code>	Animal
Animal(String, int)		
isOlder(Animal)		

Dog(String, int)	Dog
getNoise() toString()	

Explicit casts: unary prefix operators

10

Principle: you may cast an object to the name of any partition that occurs within it —and to nothing else.

`a0` maybe cast to `Object`, `Animal`, `Cat`.

An attempt to cast it to anything else causes an exception

`(Cat) c`

`(Object) c`

`(Animal) (Animal) (Cat) (Object) c`

These casts don't take any time. The object does not change. It's a change of perception

<code>a0</code>	
<code>equals() ...</code>	<code>Object</code>
<code>age</code> <code>5</code>	<code>Animal</code>
<code>Animal(String, int)</code> <code>isOlder(Animal)</code>	
<code>Cat(String, int)</code> <code>getNoise() toString()</code> <code>getWeight()</code>	<code>Cat</code>

`c` `a0`
Cat

Static/dynamic types

11

```
public class Animal {  
    /** = "this is older than h" */  
    public boolean isOlder(Animal h) {  
        return age > h.age;  
    }  
}
```

Static or **apparent** type of `h` is `Animal`. Syntactic property
Determines at compile-time what components can be used: those available in `Animal`

`h` `a1`
Animal

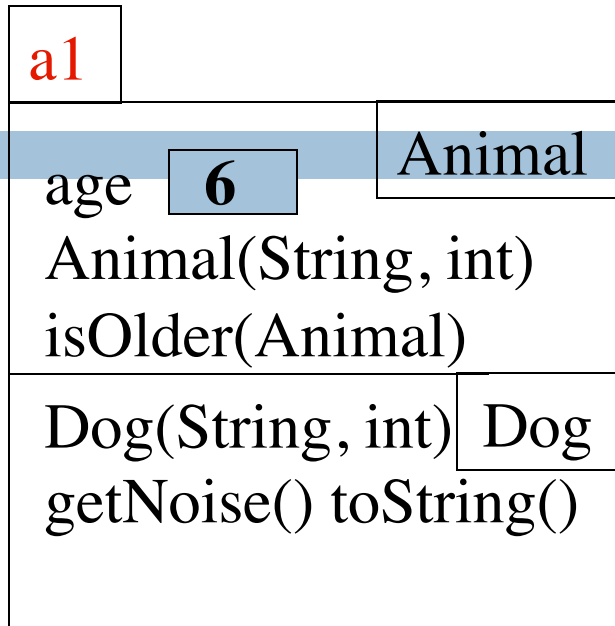

Dynamic or **real** type of `h` is `Dog`. Semantic/runtime property
If a method call is legal, dynamic type determines which one is called (overriding one)

Components used from h

12

```
public class Animal {  
    /** = "this is older than h" */  
    public boolean isOlder(Animal h) {  
        return age > h.age;  
    }  
}
```

h.toString() OK —it's in class **Object** partition
h.isOlder(...) OK —it's in **Animal** partition
h.getWeight() **ILLEGAL** —not in **Animal**
partition or **Object** partition

By overriding
rule, calls
toString() in
Cat partition

h

a1

Animal

Explicit downward cast

13

```
public class Animal {  
    // If Animal is a Cat, return its weight;  
    // otherwise, return 0.  
    public int checkWeight(Animal h) {  
        if ( !  
            )  
            return 0;  
        // { h is a Cat }  
        Cat c= (Cat) h ; // downward cast  
        return c.getWeight();  
    }  
}
```

h a0
Animal

a0

age 5	Animal
Animal(String, int) isOlder(Animal)	

Cat(String, int)	Cat
getNoise() toString() getWeight()	

(Dog) h leads to runtime error.

Don't try to cast an object to something that it is not!

Operator instanceof, explicit downward cast

14

```
public class Animal {  
    // If Animal is a cat, return its weight;  
    // otherwise, return 0.  
    public int checkWeight(Animal h) {  
        if ( ! (h instanceof Cat) )  
            return 0;  
        // { h is a Cat }  
        Cat c= (Cat) h ; // downward cast  
        return c.getWeight();  
    }  
}
```

h a0
Animal

a0

age 5	Animal
Animal(String, int) isOlder(Animal)	
Cat(String, int)	Cat
getNoise() toString() getWeight()	

<object> instanceof <class>

true iff **object** is an instance of the **class** —if **object** has a partition for **class**

Function equals

15

```
public class Object {  
    /** Return true iff this object is the same as ob */  
    public boolean equals(Object b) {  
        return this == b;  
    }  
}
```

`x.equals(y)` is same as
`x == y`
except when `x` is null!

This gives a null-pointer
exception:

`null.equals(y)`

Overriding function equals

16

Override function **equals** in a class to give meaning to:

“these two (possibly different) objects of the class have the same values in some of their fields”

For those who are mathematically inclined, like any equality function, **equals** should be reflexive, symmetric, and transitive.

Reflexive: `b.equals(b)`

Symmetric: `b.equals(c) = c.equals(b)`

Transitive: if `b.equals(c)` and `c.equals(d)`, then `b.equals(d)`

Function equals in class Animal

17

a0

```
public class Animal {  
    /** = "h is an Animal with the same  
        values in its fields as this Animal" */  
    public boolean equals (Object h) {  
        if (!(h instanceof Animal))  
            return false;  
        Animal ob= (Animal) h;  
        return name.equals(ob.name) &&  
            age == ob.age;  
    }  
}
```

	Object
equals(Object)	
toString()	Animal
name <input type="text"/>	age <input type="text"/>
Animal(String, int)	
equals()	
toString()	
...	

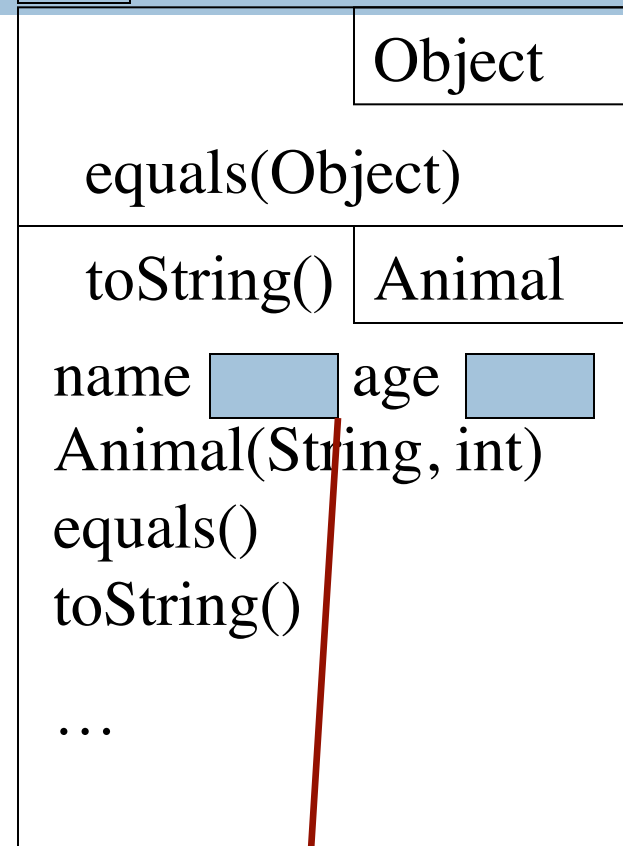

1. Because of **h is an Animal** in spec,
need the test **h instanceof Animal**

Function equals in class Animal

18

```
public class Animal {  
    /** = "h is an Animal with the same  
        values in its fields as this Animal" */  
    public boolean equals (Object h) {  
        if (!(h instanceof Animal))  
            return false;  
        Animal ob= (Animal) h;  
        return name.equals(ob.name) &&  
            age == ob.age;  
    }  
}
```

a0

2. In order to be able to reference fields in partition **Animal**,
need to cast h to **Animal**

Function equals in class Animal

19

```
public class Animal {  
    /** = "h is an Animal with the same  
        values in its fields as this Animal" */  
    public boolean equals (Object h) {  
        if (!(h instanceof Animal))  
            return false;  
        Animal ob= (Animal) h;  
        return name.equals(ob.name) &&  
            age == ob.age;  
    }  
}
```

a0

3. Use **String equals** function to check for equality of **String** values. Use **==** for primitive types

Why can't the parameter type be Animal?

20

a0

```
public class Animal {  
    /** = "h is an Animal with the same  
        values in its fields as this Animal" */  
    public boolean equals (Animal h) {  
        if (!(h instanceof Animal))  
            return false;  
        Animal ob= (Animal) h;  
        return name.equals(ob.name) &&  
            age == ob.age;  
    }  
}
```

What is wrong with this?

Recitation this week: VERY important

21

Recitation this week is about

abstract classes

interfaces

Don't miss
recitation

Learn:

- Why we may want to make a class abstract
- Why we may want to make a method abstract
- An interface is like a very restricted abstract class, with different syntax for using it.
