

This recitation

- An interesting point about A2: Using previous methods to avoid work in programming and debugging. How much time did *you* spend writing and debugging prepend?
- Enums (enumerations)
- Generics and Java's Collection interfaces and classes
- Parsing arithmetic expressions using a grammar that gives precedence to * and / over + and - (if there is time)

How to use previous methods in A2

The A2 handout contained this:

Further guidelines and instructions!

“Note that some methods that you have to write **Also, in writing methods 4..7, writing them in terms of calls on previously written methods may save you time.**”

Did you read that? Think about it? Attempt it?

A lesson in:

1. Reading carefully, wisely.
2. Thinking about what methods do, visualizing what they do.

Suppose we want to append e to this list:

This is what it looks like after the append:

What if we prepended e instead of appending it?

Legend

What append does:

What prepend does:

Therefore: `prepend(v)`; can be done by

`append(v); head= head.pred;`

body of prepend

What append
does

What prepend
does

prepend(v) is simply `append(v); head= head.pred;`

How much time did you
spend writing and debug-
ging prepend?

Did you try to write
prepend in terms of
append?

Morals of the story:

1. Read carefully.
2. Visualize what methods do;
understand specs completely.
3. Avoid duplication of effort by
using previously written
methods

About enums (enumerations)

An enum: a class that lets you create mnemonic names for entities instead of having to use constants like 1, 2, 3, 4

The declaration below declares a class **Suit**.

After that, in any method, use **Suit.Clubs**, **Suit.Diamonds**, etc. as constants.

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

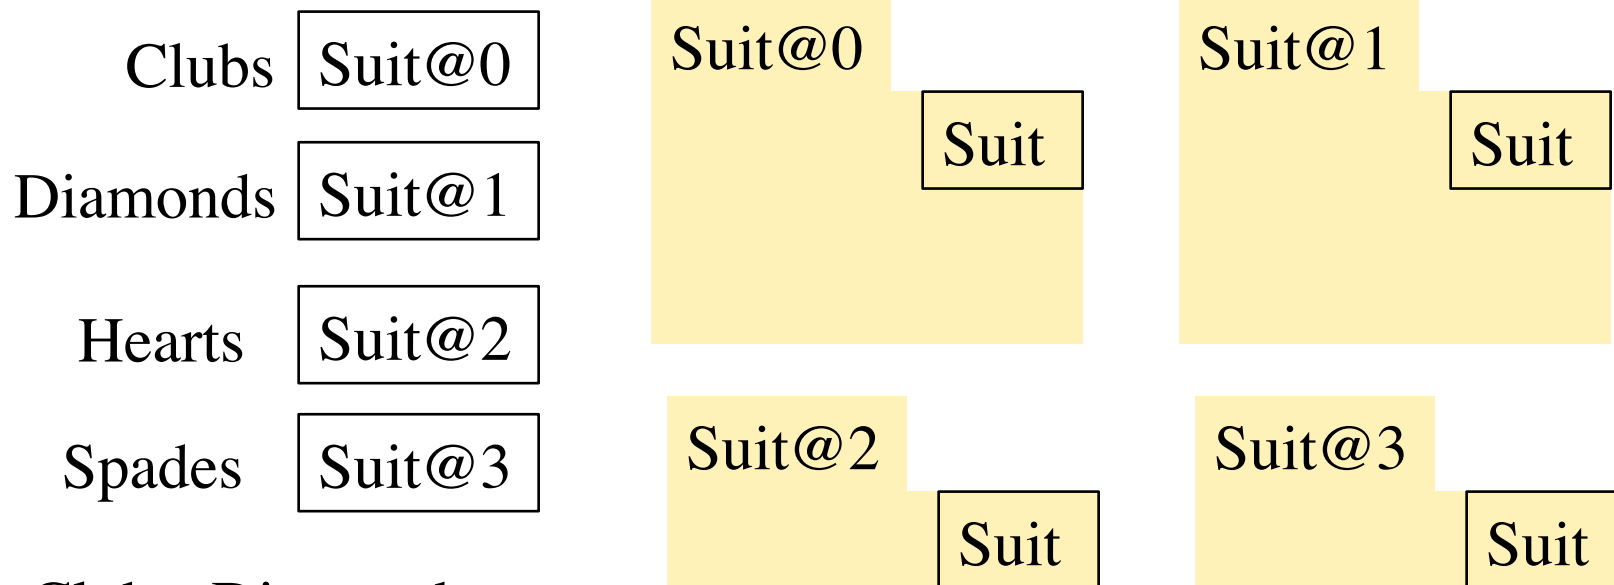

could be private,
or any access
modifier

new
keyword

The constants of the class
are **Clubs**, **Diamonds**,
Hearts, **Spades**

Four static final variables that contain pointers to objects

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

Clubs, Diamonds,
Hearts, Spades
Are static variables of
class enum

Testing for an enum constant

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

```
Suit s= Suit.Clubs;
```

Then

```
s == Suit.Clubs is true
```

```
s == Suit.Hearts is false
```

```
switch(s) {  
  case Clubs:  
  case Spades:  
    color= "black"; break;  
  case Diamonds:  
  case Hearts:  
    color= "red"; break;  
}
```

Can use a switch statement

Type of **s** is **Suit**.

Inside the switch,
you **cannot** write
Suit.Hearts instead
of **Hearts**

Miscellaneous points about enums

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

This declaration is shorthand for a class that has a constructor, four constants (public static final variables), a static method, and some other components. Here are some points:

1. **Suit** is a subclass of **Enum** (in package **java.lang**)
2. It is not possible to create instances of class **Suit**, because its constructor is private!
3. It's as if **Clubs** (as well as the other three names) is declared within class **Suit** as

```
public static final Suit Clubs= new Suit(some values);
```

You don't care what values

Miscellaneous points about enums

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

4. Static function `values()` returns a `Suit[]` containing the four constants. You can, for example, use it to print all of them:

```
for (Suit s : Suit.values())  
    System.out.println(s);
```

`toString` in object `Clubs` returns the string `"Clubs"`

Output:
Clubs
Diamonds
Hearts
Spades

Can save this array in a static variable and use it over and over:

```
private static Suit[] mine= Suit.values();
```

Miscellaneous points about enums

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

5. Static function `valueOf(String name)` returns the enum constant with that name:

```
Suit c= Suit.valueOf("Hearts");
```

After the assignment, c contains (the name of) object Hearts

c Suit@2

This is the object for Hearts:

Suit@2

Suit

Miscellaneous points about enums

```
public enum Suit {Clubs, Diamonds, Hearts, Spades}
```

This declaration is shorthand for a class that has a constructor, four constants (public static final variables), a static method, and some other components. Here are some points:

6. Object Clubs (and the other three) has a function ordinal() that returns its position in the list

```
Suit.Clubs.ordinal()    is 0  
Suit.Diamonds.ordinal() is 1
```

We have only touched the surface of enums. E.g. in an enum declaration, you can write a private constructor, and instead of **Clubs** you can put a more elaborate structure. All this is outside the scope of CS2110.

Package `java.util` has a bunch of classes called the **Collection Classes** that make it easy to maintain sets of values, list of values, queues, and so on. You should spend some time looking at their API specifications and getting familiar with them.

Remember:

A **set** is a bunch of distinct (different) values. No ordering is implied

A **list** is an ordered bunch of values. It may have duplicates.

Interface Collection: abstract methods for dealing with a group of objects (e.g. sets, lists)

Abstract class AbstractCollection: overrides some abstract methods with methods to make it easier to fully implement **Collection**

AbstractList, AbstractQueue, AbstractSet, AbstractDeque overrides some abstract methods of **AbstractCollection** with real methods to make it easier to fully implement **lists, queues, set, and deque**s

Next slide contains classes that you should become familiar with and use. Spend time looking at their specifications. There are also other useful **Collection** classes

Class ArrayList extends AbstractList: An object is a growable/shrinkable list of values implemented in an array

Class HashSet extends AbstractSet: An object maintains a growable/shrinkable set of values using a technique called *hashing*. We will learn about hashing later.

Class LinkedList extends AbstractSequentialList: An object maintains a list as a doubly linked list

Class Vector extends AbstractList: An object is a growable/shrinkable list of values implemented in an array. An old class from early Java

Class Stack extends Vector: An object maintains LIFO (last-in-first-out) stack of objects

Class Arrays: Has lots of static methods for dealing with arrays — searching, sorting, copying, etc.

ArrayList

`ArrayList v = new ArrayList ();`

defined in package `java.util`

An object of class `ArrayList` contains a [growable/shrinkable](#) list of elements (of class `Object`). You can get the size of the list, add an object at the end, remove the last element, get element `i`, etc. [More methods exist! Look at them!](#)

v `ArrayList@x1`

Vector

`ArrayList@x1`

`Object`

Fields that `ArrayList` contain a list of objects
(`o0, o1, ..., osize()-1`)

`ArrayList ()` `add(Object)`
`get(int)` `size()`
`remove(...)` `set(int, Object)`
...

HashSet

```
HashSet s= new HashSet();
```

An object of class **HashSet** contains a **growable/shrinkable** set of elements (of class **Object**). You can get the size of the set, add an object to the set, remove an object, etc. **More methods exist! Look at them!**

```
s HashSet@y2
```

HashSet

Don't ask what "hash" means. Just know that a Hash Set object maintains a set

HashSet@y2

Object

Fields that

HashSet

contain a set of objects

$\{o_0, o_1, \dots, o_{\text{size}()-1}\}$

HashSet() add(Object)

contains(Object) size()

remove(Object)

...

Iterating over a HashSet or ArrayList

```
HashSet s= new HashSet();  
... code to store values in the set ...  
for (Object e : s) {  
    System.out.println(c);  
}
```

A loop whose body is executed once with **e** being each element of the set. Don't know order in which set elements processed

Use same sort of loop to process elements of an **ArrayList** in the order in which they are in the **ArrayList** .

HashSet@y2

Object

Fields that **HashSet** contain a setof objects

$\{o_0, o_1, \dots, o_{\text{size}()-1}\}$

HashSet() add(Object)
contains(Object) size()
remove(Object)

...

s HashSet@y2

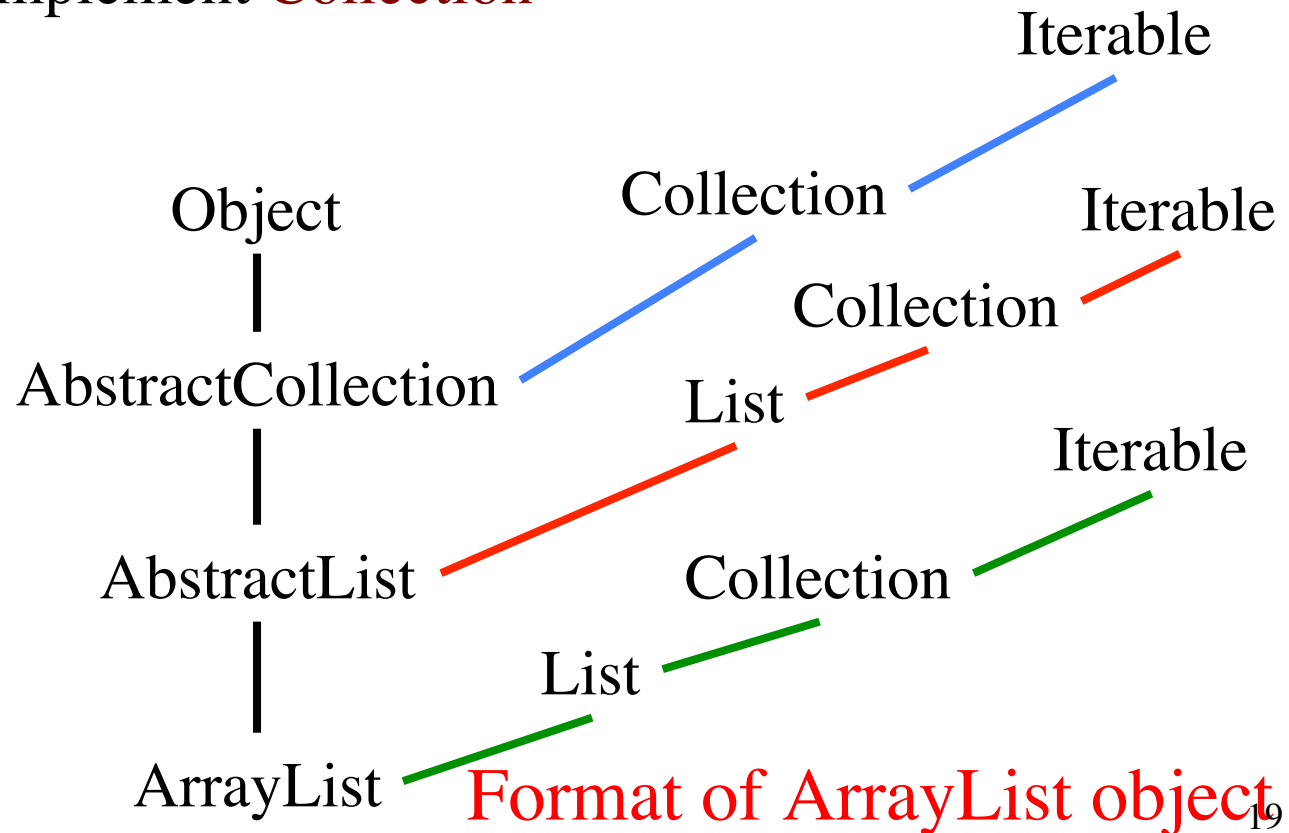

HashSet

Interface Collection: abstract methods for dealing with a group of objects (e.g. sets, lists)

Iterable
Not discussed today

Abstract class AbstractCollection: overrides some abstract methods with real methods to make it easier to fully implement **Collection**

ArrayList implements 3 other interfaces, not shown

Format of ArrayList object₁₉

Interface List: abstract methods for dealing with a list of objects (o_0, \dots, o_{n-1}). **Examples:** arrays, Vectors

Iterable
Not
discussed
today

Abstract class AbstractList: overrides some abstract methods with real methods to make it easier to fully implement **List**

Homework:
Look at API
specifications
and build
diagram giving
format of
HashSet

Generics and Java's Collection Classes

ge·ner·ic *adjective* \jə·'nerik, -rēk\

relating or applied to or descriptive of all members of a genus, species, class, or group: common to or characteristic of a whole group or class: typifying or subsuming: not specific or individual.

From Wikipedia: **generic programming**: a style of computer programming in which algorithms are written in terms of to-be-specified-later types that are then *instantiated* when needed for **specific types provided as parameters**.

Read carefully!

In Java: Without generics, every **Vector** object contains a list of elements of class **Object**. Clumsy

With generics, we can have a **Vector** of **Strings**, a **Vector** of **Integers**, a **Vector** of **Genes**. **Simplifies programming, guards against some errors**

Generics: say we want an ArrayList of only one class

API specs: ArrayList declared like this:

```
public class ArrayList <E> extends AbstractList<E>  
    implements List<E> ... { ... }
```

Means:

Can create Vector specialized to certain class of objects:

```
ArrayList <String> vs= new ArrayList <String>(); //only Strings
```

```
ArrayList <Integer> vi= new ArrayList <Integer>(); //only Integers
```

```
vs.add(3);
```

```
vi.add("abc");
```

These are illegal

```
int n= vs.get(0).size();
```

vs.get(0) has type String

No need to cast

ArrayList to maintain list of Strings is cumbersome

```
ArrayList v= new ArrayList ();
```

```
... Store a bunch of Strings in v ...
```

— Only Strings, nothing else

```
// Get element 0, store its size in n
```

```
String ob= ((String) v.get(0)).length();  
int n= ob.size();
```

All elements of **v** are of type **Object**.
So, to get the size of element 0, you
first have to cast it to **String**.

Make mistake, put an Integer in v?
May not catch error for some time.

```
v ArrayList@x1 ArrayList
```

ArrayList @x1

Object

Fields that **ArrayList**
contain a list of objects
($o_0, o_1, \dots, o_{\text{size}()-1}$)

Vector()	add(Object)
get(int)	size()
remove()	set(int, Object)
...	

Generics allow us to say we want Vector of Strings only

API specs: Vector declared like this:

```
public class Vector<E> extends AbstractList<E>  
                    implements List<E> ... { ... }
```

Full understanding of generics is not given in this recitation.

E.g. We do not show you how to write a generic class.

Important point: When you want to use a class that is defined like *Vector* above, you can write

```
Vector<C> v = new Vector<C>(...);
```

to have *v* contain a *Vector* object whose elements **HAVE** to be of class *C*, and when retrieving an element from *v*, its class is *C*.

Parsing Arithmetic Expressions

Introduced in lecture briefly, to show use of grammars and recursion. Done more thoroughly and carefully here.

We show you a real grammar for arithmetic expressions with integer operands; operations $+$, $-$, $*$, $/$; and parentheses $()$. It gives precedence to multiplicative operations.

We write a recursive descent parser for the grammar and have it generate instructions for a stack machine (explained later). You learn about infix, postfix, and prefix expressions.

Historical note: Gries wrote the first text on compiler writing, in 1971. It was the first text written/printed on computer, using a simple formatting application. It was typed on punch cards. You can see the cards in the Stanford museum; visit infolab.stanford.edu/pub/voy/museum/pictures/display/floor5.htm

Parsing Arithmetic Expressions

$-5 + 6$ Arithmetic expr in infix notation

$5 - 6 +$ Same expr in postfix notation

infix: operation between operands

postfix: operation after operands

prefix: operation before operands

PUSH 5

NEG

PUSH 6

ADD

Corresponding machine language for a “stack machine”:

PUSH: push value on stack

NEG: negate the value on top of stack

ADD: Remove top 2 stack elements, push their sum onto stack

Infix requires parentheses. Postfix doesn't

$(5 + 6) * (4 - 3)$	Infix
$5\ 6\ +\ 4\ 3\ -\ *$	Postfix
$5 + 6 * 3$	Infix
$5\ 6\ 3\ * +$	Postfix

Math convention: * has precedence over +. This convention removes need for many parentheses

Task: Write a parser for conventional arithmetic expressions whose operands are ints.

1. **Need a grammar for expressions**, which defines legal arith exps, giving precedence to * / over + -
2. **Write recursive procedures**, based on grammar, to parse the expression given in a String. Called a **recursive descent parser**

Use 3 syntactic categories: $\langle \text{Exp} \rangle$, $\langle \text{Term} \rangle$, $\langle \text{Factor} \rangle$ **Grammar**

A $\langle \text{Factor} \rangle$ has one of 3 forms:

1. integer
2. $-\langle \text{Factor} \rangle$
3. $(\langle \text{Exp} \rangle)$

Show “syntax trees” for
3 $--5$ $-(3+2)$

$\langle \text{Factor} \rangle ::= \text{int}$
 | $\langle \text{Factor} \rangle$
 | $(\langle \text{Exp} \rangle)$

Haven't shown
 $\langle \text{Exp} \rangle$
grammar
yet

Use 3 syntactic categories: $\langle \text{Exp} \rangle$, $\langle \text{Term} \rangle$, $\langle \text{Factor} \rangle$ **Grammar**

A $\langle \text{Term} \rangle$ is:

$\langle \text{Factor} \rangle$ followed by 0 or more occurs. of **multop** $\langle \text{Factor} \rangle$
where **multop** is * or /

Means: 0 or 1 occurrences of * or /

$\langle \text{Term} \rangle ::= \langle \text{Factor} \rangle \{ \{ * \mid / \}^1 \langle \text{Factor} \rangle \}$

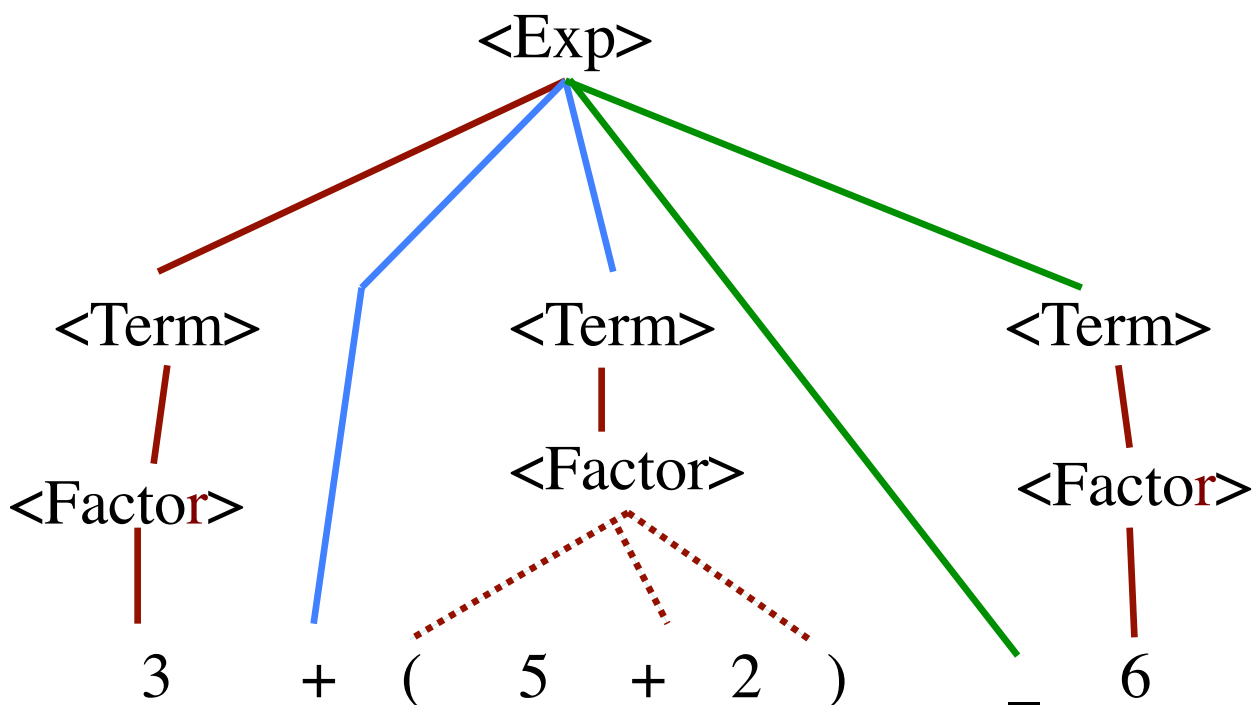

Means: 0 or more occurrences of thing inside { }

Use 3 syntactic categories: $\langle \text{Exp} \rangle$, $\langle \text{Term} \rangle$, $\langle \text{Factor} \rangle$ **Grammar**

A $\langle \text{Exp} \rangle$ is:

$\langle \text{Term} \rangle$ followed by 0 or more occurrences of **addop** $\langle \text{Term} \rangle$
where **addop** is + or -

$\langle \text{Exp} \rangle ::= \langle \text{Term} \rangle \{ \{ + \mid - \}^1 \langle \text{Term} \rangle \}$

Class Scanner

Initialized to a String that contains an arithmetic expression.
Delivers the **tokens** in the String, one at a time

Expression: 3445*(20 + 16)

Tokens:

3445

*

(

20

+

16

)

All parsers use a scanner,
so they do not have to
deal with the input
character by character
and do not have to deal
with whitespace

An instance provides tokens from a string, one at a time.

A token is either

1. an unsigned integer,
2. a Java identifier
3. an operator + - * / %
4. a paren of some sort: () [] { }
5. any seq of non-whitespace chars not included in 1..4.

Class Scanner

```
public Scanner(String s)           // An instance with input s
public boolean hasToken()         // true iff there is a token in input
public String token()            // first token in input (null if none)
public String scanOverToken()    // remove first token from input
                                   // and return it (null if none)
public boolean tokenIsInt()      // true iff first token in input is int
public boolean tokenIsId()      // true iff first token in input is a
                                   // Java identifier
```

```
/** scanner's input should start with a <Factor>
    —if not, throw a RuntimeException.
```

**Parser for
<Factor>**

```
Return the postfix instructions for <Factor>
and have scanner remove the <Factor> from its input.
```

```
<Factor> ::= an integer
```

```
    | - <Factor>
```

```
    | ( <Expr> ) */
```

```
public static String parseFactor(Scanner scanner)
```

The spec of every parser method for a grammatical entry is similar. It states

1. What is in the scanner when parsing method is called
2. What the method returns.
3. What was removed from the scanner during parsing.

/** scanner's input should start with an <Exp>
--if not throw a RuntimeException.

**Parser for
<Exp>**

Return corresponding postfix instructions
and have scanner remove the <Exp> from its input.

<Exp> := <Term> { {+ or -}1 <Term> } */

```
public static String parseExp(Scanner scanner) {  
    String code= parseTerm(scanner);  
    while ("+" .equals(scanner.token()) ||  
        "-" .equals(scanner.token())) {  
        String op= scanner.scanOverToken();  
        String rightOp= parseTerm(scanner);  
        code= code + rightOp +  
            (op.equals("+") ? "PLUS\n" : "MINUS\n");  
    }  
    return code;  
}
```
