Analysis of Algorithms and Inductive Proofs

Review: Big O definition

$f(n)$ is $O(g(n))$

iff

There exists $c > 0$ and $N > 0$

such that:

$$f(n) \leq c * g(n) \text{ for } n \geq N$$

Example: $n+6$ is $O(n)$

$n + 6$ ---this is $f(n)$
<= <if $6 \leq n$, write as>
 $n + n$
= <arith>
 $2*n$
<choose $c = 2$ >
= $c*n$ ---this is $c * g(n)$

$f(n)$ is $O(g(n))$: There exist
 $c > 0$, $N > 0$ such that:

$$f(n) \leq c * g(n) \text{ for } n \geq N$$

So choose $c = 2$ and $N = 6$

Review: Big O

Is used to classify algorithms by how they respond to changes in input size n .

Important vocabulary:

- Constant time: $O(1)$
- Logarithmic time: $O(\log n)$
- Linear time: $O(n)$
- Quadratic time: $O(n^2)$
- Exponential time: $O(2^n)$

Review: Big O

1. $\log(n) + 20$ is $O(\log(n))$ (logarithmic)
2. $n + \log(n)$ is $O(n)$ (linear)
3. $n/2$ and $3 \cdot n$ are $O(n)$
4. $n \cdot \log(n) + n$ is $n \cdot \log(n)$
5. $n^2 + 2 \cdot n + 6$ is $O(n^2)$ (quadratic)
6. $n^3 + n^2$ is $O(n^3)$ (cubic)
7. $2^n + n^5$ is $O(2^n)$ (exponential)

Merge Sort

Runtime of merge sort

```
/** Sort b[h..k]. */  
public static void mS(Comparable[] b, int h, int k) {  
    if (h >= k) return;  
    int e = (h+k)/2;  
    mS(b, h, e);  
    mS(b, e+1, k);  
    merge(b, h, e, k);  
}
```

mS is **mergeSort** for readability

Runtime of merge sort

```
/** Sort b[h..k]. */  
public static void mS(Comparable[] b, int h, int k) {  
    if (h >= k) return;  
    int e = (h+k)/2;  
    mS(b, h, e);  
    mS(b, e+1, k);  
    merge(b, h, e, k);  
}
```

mS is **mergeSort** for readability

- We will *count* the number of comparisons mS makes
- Use **$T(n)$** for the number of array element comparisons that mS makes on an array segment of size n

Runtime of merge sort

```
/** Sort b[h..k]. */  
public static void mS(Comparable[] b, int h, int k) {  
    if (h >= k) return;  
    int e = (h+k)/2;  
    mS(b, h, e);  
    mS(b, e+1, k);  
    merge(b, h, e, k);  
}
```

$$T(0) = 0$$

$$T(1) = 0$$

Use $T(n)$ for the number of array element comparisons that mergeSort makes on an array of size n

Runtime of merge sort

```

/** Sort b[h..k]. */
public static void mS (Comparable[] b, int h, int k) {
    if (h >= k) return;
    int e= (h+k)/2;
    mS (b, h, e);          T(e+1-h) comparisons = T(n/2)
    mS (b, e+1, k);       T(k-e)    comparisons = T(n/2)
    merge (b, h, e, k);   How long does merge
                           take?
}

```

Runtime of merge

pseudocode for merge

```
/** Pre: b[h..e] and b[e+1..k] are already sorted */
```

```
merge(Comparable[] b, int h, int e, int k)
```

```
  Copy both segments
```

```
  While both copies are non-empty
```

```
    Compare the first element of each segment
```

```
    Set the next element of b to the smaller value
```

```
    Remove the smaller element from its segment
```

One comparison, one add, one remove

k-h loops must empty one segment

Runtime is $O(k-h)$

Runtime of merge sort

```

/** Sort b[h..k]. */
public static void mS (Comparable[] b, int h, int k) {
    if (h >= k) return;
    int e= (h+k)/2;
    mS (b, h, e);          T(e+1-h) comparisons = T(n/2)
    mS (b, e+1, k);       T(k-e)    comparisons = T(n/2)
    merge (b, h, e, k);    O(k-h)    comparisons =
O(n)
}

```

Recursive Case:

$$T(n) = 2T(n/2) + O(n)$$

Runtime

We determined that

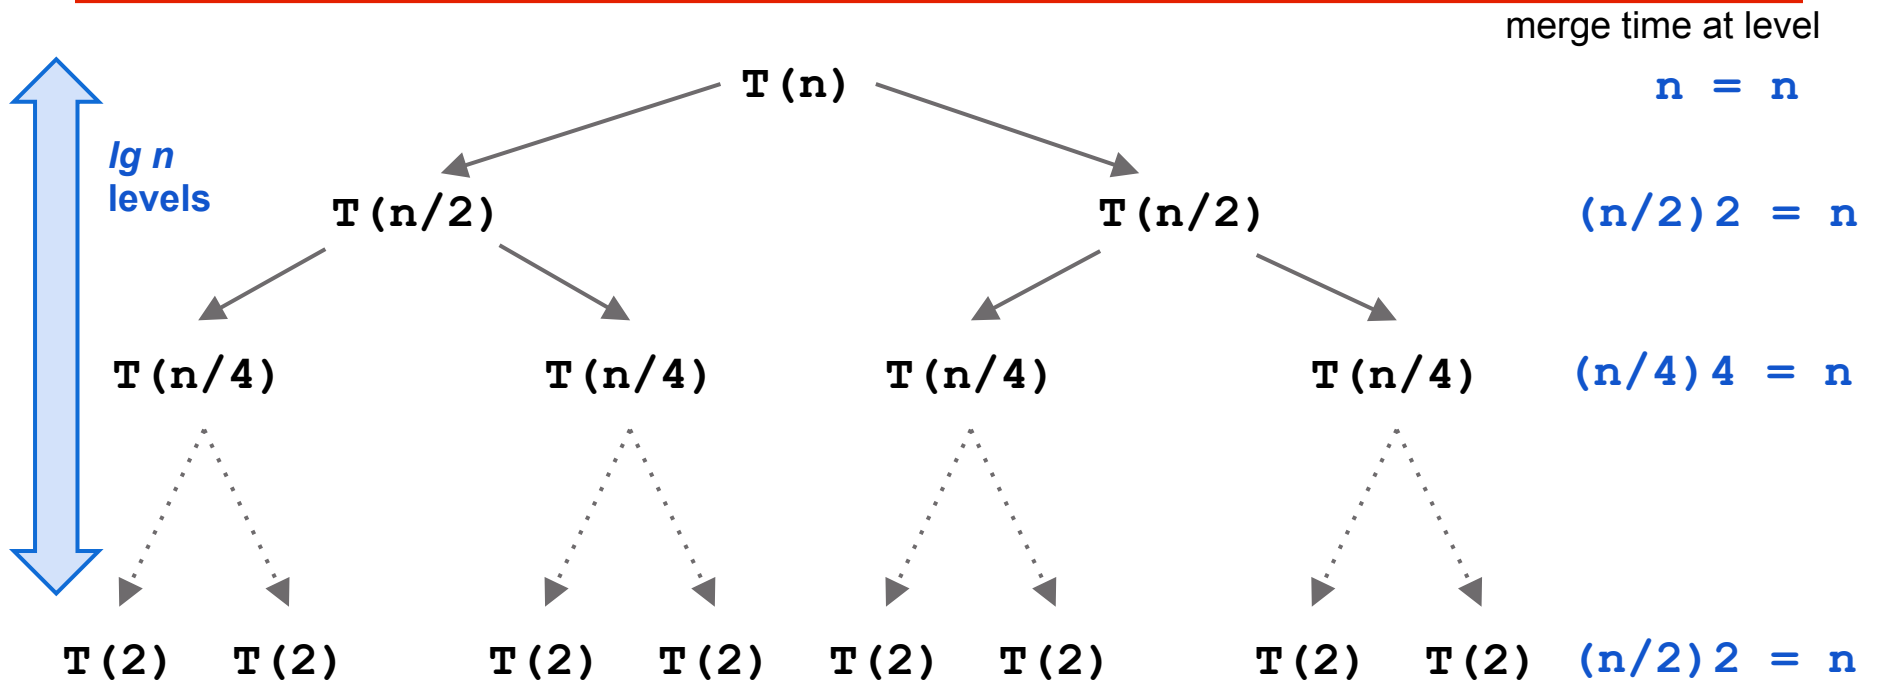

$$T(1) = 0$$

$$T(n) = 2T(n/2) + n \quad \text{for } n > 1$$

We will prove that

$$T(n) = n \log_2 n \quad (\text{or } n \lg n \text{ for short})$$

Recursion tree

$\lg n$ levels * n comparisons is $O(n \log n)$

Proof by induction

To prove $T(n) = n \lg n$,
we can assume true for smaller values of n (like recursion)

$$\begin{aligned} T(n) &= 2T(n/2) + n \\ &= 2(n/2) \lg(n/2) + n \\ &= n(\lg n - \lg 2) + n && \leftarrow \text{Property of logarithms} \\ &= n(\lg n - 1) + n && \leftarrow \log_2 2 = 1 \\ &= n \lg n - n + n \\ &= n \lg n \end{aligned}$$

Heap Sort

Heap Sort

Very simple idea:

1. Turn the array into a max-heap
2. Pull each element out

```
/** Sort b */  
public static void heapSort(Comparable[] b) {  
    heapify(b);  
    for (int i= b.length-1; i >= 0; i--) {  
        b[i]= poll(b, i);  
    }  
}
```

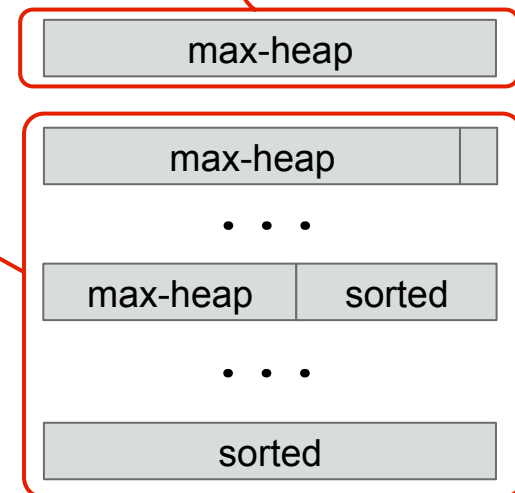

Heap Sort

```

/** Sort b */
public static void heapSort(Comparable[] b) {
    heapify(b);
    for (int i= b.length-1; i >= 0; i--) {
        b[i]= poll(b, i);
    }
}

```

Why does it have to be a max-heap?

Heap Sort runtime

```

/** Sort b */
public static void heapSort(Comparable[] b) {
    heapify(b); ← O(n lg n)
    for (int i= b.length-1; i >= 0; i--) {
        b[i]= poll(b, i); ← loops n times
    }
}
                ↑
                O(lg n)

```

Total runtime:

$$O(n \lg n) + n * O(\lg n) = O(n \lg n)$$
