

# PRIORITY QUEUES AND HEAPS

Lecture 17  
CS2110 Spring 2016

# Readings and Homework

2

**Read Chapter 26** “A Heap Implementation” to learn about heaps

**Exercise:** Salespeople often make matrices that show all the great features of their product that the competitor’s product lacks. Try this for a heap versus a BST. First, try and sell someone on a BST: List some desirable properties of a BST that a heap lacks. Now be the heap salesperson: List some good things about heaps that a BST lacks. Can you think of situations where you would favor one over the other?

***With ZipUltra heaps, you’ve got it made in the shade my friend!***

# Stacks and queues are restricted lists

3

- Stack (**LIFO**) implemented as list
  - **add ()**, **remove ()** from front of list (push and pop)
- Queue (**FIFO**) implemented as list
  - **add ()** on back of list, **remove ()** from front of list
- These operations are  $O(1)$

Both efficiently implementable using a singly linked list with head and tail

# Interface Bag (not In Java Collections)

4

```
interface Bag<E>
    implements Iterable {
    void add(E obj);
    boolean contains(E obj);
    boolean remove(E obj);
    int size();
    boolean isEmpty();
    Iterator<E> iterator()
}
```

Also called **multiset**

Like a set except that a value can be in it more than once. Example: a bag of coins

Refinements of Bag: Stack, Queue, PriorityQueue

# Priority queue

5

- **Bag** in which data items are **Comparable**
- **Smaller** elements (determined by **compareTo ()**) have **higher** priority
- **remove ()** return the element with the highest priority = least element in the **compareTo ()** ordering
- break ties arbitrarily

# Many uses of priority queues (& heaps)

6

Surface simplification [Garland and Heckbert 1997]

- Event-driven simulation: customers in a line
- Collision detection: "next time of contact" for colliding bodies
- Graph searching: Dijkstra's algorithm, Prim's algorithm
- AI Path Planning: A\* search
- Statistics: maintain largest  $M$  values in a sequence
- Operating systems: load balancing, interrupt handling
- Discrete optimization: bin packing, scheduling

# java.util.PriorityQueue<E>

7

```
interface PriorityQueue<E> { TIME  
    boolean add(E e) {...} //insert e. log  
    void clear() {...} //remove all elems.  
    E peek() {...} //return min elem. constant  
    E poll() {...} //remove/return min elem. log  
    boolean contains(E e) linear  
    boolean remove(E e) linear  
    int size() {...} constant  
    Iterator<E> iterator()  
}
```

# Priority queues as lists

8

- Maintain as **unordered list**
  - **add()** put new element at front –  $O(1)$
  - **poll()** must search the list –  $O(n)$
  - **peek()** must search the list –  $O(n)$
- Maintain as **ordered list**
  - **add()** must search the list –  $O(n)$
  - **poll()** wanted element at top –  $O(1)$
  - **peek()**  $O(1)$

Can we do better?

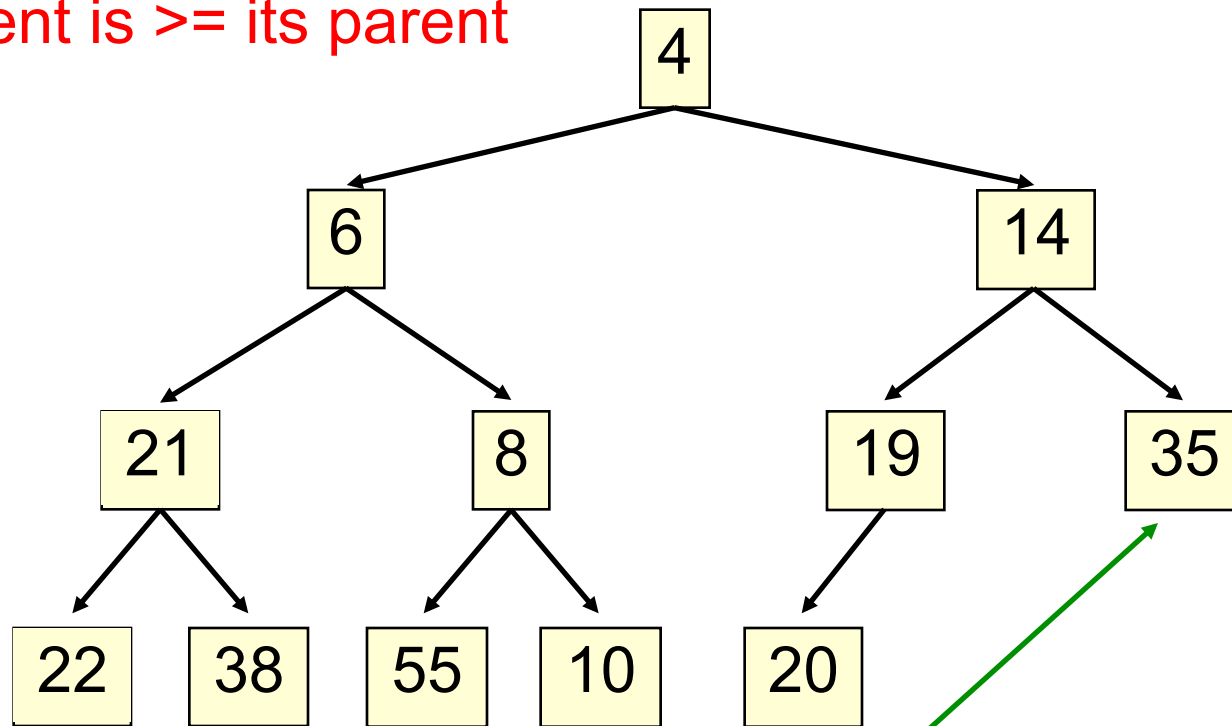

# Heap

9

- A *heap* is a concrete data structure that can be used to implement priority queues
- Gives better complexity than either ordered or unordered list implementation:
  - **add ()** :  $O(\log n)$  (n is the size of the heap)
  - **poll ()** :  $O(\log n)$
- $O(n \log n)$  to process n elements
- Do not confuse with *heap memory*, where the Java virtual machine allocates space for objects – different usage of the word *heap*

# Heap: first property

Every element is  $\geq$  its parent

Note: 19, 20 < 35: Smaller elements can be deeper in the tree!

# Heap: second property: is complete, has no holes

Every level (except last) completely filled.

Nodes on bottom level are as far left as possible.

# Heap: Second property: has no “holes”

Not a heap because it has two holes

Not a heap because:

- missing a node on level 2
- bottom level nodes are not as far left as possible

# Heap

13

- Binary tree with data at each node
- Satisfies the *Heap Order Invariant*:

1. Every element is  $\geq$  its parent.

- Binary tree is **complete** (no holes)

2. Every level (except last) completely filled.  
Nodes on bottom level are as far left as possible.

# Numbering the nodes in a heap

Number node starting at root in breadth-first left-right order

Children of node  $k$  are nodes  $2k+1$  and  $2k+2$   
Parent of node  $k$  is node  $(k-1)/2$

# Can store a heap in an array b (could also be ArrayList or Vector)

15

- Heap nodes in b in order, going across each level from left to right, top to bottom
- Children of  $b[k]$  are  $b[2k + 1]$  and  $b[2k + 2]$
- Parent of  $b[k]$  is  $b[(k - 1)/2]$

Tree structure is implicit.  
No need for explicit links!

# add (e)

# add (e)

17

1. Put in the new element in a new node

# add ()

18

2. Bubble new element up if less than parent

# add ()

19

2. Bubble new element up if less than parent

# add ()

# add ()

21

1. Put in the new element in a new node

# add ()

22

2. Bubble new element up if less than parent

# add ()

23

2. Bubble new element up if less than parent

# add ()

24

2. Bubble new element up if less than parent

# add ()

# add (e)

26

- Add e at the end of the array
- Bubble e up until it no longer violates heap order
- The heap invariant is maintained!

# add() to a tree of size n

27

- Time is  $O(\log n)$ , since the tree is balanced
  - size of tree is exponential as a function of depth
  - depth of tree is logarithmic as a function of size

# add() --assuming there is space

28

```
/** An instance of a heap */
class Heap<E> {
    E[] b= new E[50]; // heap is b[0..n-1]
    int n= 0; // heap invariant is true

    /** Add e to the heap */
    public void add(E e) {
        b[n]= e;
        n= n + 1;
        bubbleUp(n - 1); // given on next slide
    }
}
```

## add () . Remember, heap is in b[0..n-1]

29

```
class Heap<E> {
    /** Bubble element #k up to its position.
     * Pre: heap inv holds except maybe for k */
    private void bubbleUp(int k) {
        int p= (k-1)/2;
        // inv: p is parent of k and every elmnt
        // except perhaps k is >= its parent
        while (k > 0 && b[k].compareTo(b[p]) < 0) {
            swap(b[k], b[p]);
            k= p;
            p= (k-1)/2;
        }
    }
}
```

# poll()

30

# poll()

31

1. Save top element in a local variable

# poll()

32

2. Assign last value to the root, delete last value from heap

poll()

33

3. Bubble root value down

# poll()

34

3. Bubble root value down

# poll()

35

3. Bubble root value down

# poll()

36

1. Save top element in a local variable

# poll()

37

2. Assign last value to the root, delete last value from heap

# poll()

38

2. Assign last value to the root, delete last value from heap

# poll()

39

3. Bubble root value down

# poll()

40

3. Bubble root value down

# poll()

41

3. Bubble root value down

# poll()

42

# poll()

43

3. Bubble root value down

# poll ()

44

- Remove and save the least element – (at the root)
- This leaves a hole at the root – Move last element of the heap to the root.
- Bubble element down –always with smaller child, until heap invariant is true again.
- The heap invariant is maintained!

**Time is  $O(\log n)$ , since the tree is balanced**

## **poll () . Remember, heap is in b[0..n-1]**

45

```
/** Remove and return the smallest element
 * (return null if list is empty) */
public E poll() {
    if (n == 0) return null;
    E v= b[0];    // smallest value at root.
    n= n - 1;    // move last
    b[0]= b[n];  // element to root
    bubbleDown(0);
    return v;
}
```

## c's smaller child

46

```
/** Tree has n node.  
 * Return index of smaller child of node k  
 * (2k+2 if k >= n) */  
public int smallerChild(int k, int n) {  
    int c = 2*k + 2;    // k's right child  
    if (c >= n || b[c-1].compareTo(b[c]) < 0)  
        c = c-1;  
    return c;  
}
```

47

```
/** Bubble root down to its heap position.  
    Pre: b[0..n-1] is a heap except maybe b[0] */  
private void bubbleDown() {  
    int k= 0;  
    int c= smallerChild(k, n);  
    // inv: b[0..n-1] is a heap except maybe b[k] AND  
    //       b[c] is b[k]'s smallest child  
    while ( c < n && b[k].compareTo(b[c]) > 0) {  
        swap(b[k], b[c]);  
        k= c;  
        c= smallerChild(k, n);  
    }  
}
```

# Change heap behaviour a bit

48

Separate priority from value and do this:

```
add(e, p); //add element e with priority p (a double)
```

**THIS IS EASY!**

Be able to change priority

```
change(e, p); //change priority of e to p
```

**THIS IS HARD!**

**Big question:** How do we find e in the heap?

Searching heap takes time proportional to its size! **No good!**

Once found, change priority and bubble up or down. **OKAY**

**Assignment A6:** implement this heap! Use a second data structure to make change-priority expected log n time

# HeapSort(b, n) —Sort $b[0..n-1]$

49

**Whet your appetite** –use heap to get exactly  $n \log n$  in-place sorting algorithm. 2 steps, each is  $O(n \log n)$

1. Make  $b[0..n-1]$  into a **max**-heap (in place)
2. for ( $k = n-1; k > 0; k = k-1$ ) {  
     $b[k] = \text{poll}$  –i.e. take max element out of heap.  
}

We'll post this algorithm on course website

A **max**-heap has max value at root
