

## 1 Lambda calculus evaluation

There are many different evaluation strategies for the  $\lambda$ -calculus. The most permissive is *full  $\beta$  reduction*, which allows any *redex*—i.e., any expression of the form  $(\lambda x. e_1) e_2$ —to step to  $e_1\{e_2/x\}$  at any time. It is defined formally by the following small-step operational semantics rules:

$$\frac{e_1 \rightarrow e'_1}{e_1 e_2 \rightarrow e'_1 e_2} \quad \frac{e_2 \rightarrow e'_2}{e_1 e_2 \rightarrow e_1 e'_2} \quad \frac{e_1 \rightarrow e'_1}{\lambda x. e_1 \rightarrow \lambda x. e'_1} \quad \beta \frac{}{(\lambda x. e_1) e_2 \rightarrow e_1\{e_2/x\}}$$

The *call by value* (CBV) strategy enforces a more restrictive strategy: it only allows an application to reduce after its argument has been reduced to a value (i.e., a  $\lambda$ -abstraction) and does not allow evaluation under a  $\lambda$ . It is described by the following small-step operational semantics rules (here we show a left-to-right version of CBV):

$$\frac{e_1 \rightarrow e'_1}{e_1 e_2 \rightarrow e'_1 e_2} \quad \frac{e_2 \rightarrow e'_2}{v_1 e_2 \rightarrow v_1 e'_2} \quad \beta \frac{}{(\lambda x. e_1) v_2 \rightarrow e_1\{v_2/x\}}$$

Finally, the *call by name* (CBN) strategy allows an application to reduce even when its argument is not a value but does not allow evaluation under a  $\lambda$ . It is described by the following small-step operational semantics rules:

$$\frac{e_1 \rightarrow e'_1}{e_1 e_2 \rightarrow e'_1 e_2} \quad \beta \frac{}{(\lambda x. e_1) e_2 \rightarrow e_1\{e_2/x\}}$$

## 2 Confluence

It is not hard to see that the full  $\beta$  reduction strategy is non-deterministic. This raises an interesting question: does the choices made during the evaluation of an expression affect the final result? The answer turns out to be no: full  $\beta$  reduction is *confluent* in the following sense:

**Theorem** (Confluence). *If  $e \rightarrow^* e_1$  and  $e \rightarrow^* e_2$  then there exists  $e'$  such that  $e_1 \rightarrow^* e'$  and  $e_2 \rightarrow^* e'$ .*

Confluence can be depicted graphically as follows:

Confluence is often also called the Church-Rosser property.

### 3 Substitution

Each of the evaluation relations for  $\lambda$ -calculus has a  $\beta$  defined in terms of a substitution operation on expressions. Because the expressions involved in the substitution may share some variable names (and because we are working up to  $\alpha$ -equivalence) the definition of this operation is slightly subtle and defining it precisely turns out to be trickier than might first appear.

As a first attempt, consider an obvious (but incorrect) definition of the substitution operator. Here we are substituting  $e$  for  $x$  in some other expression:

$$\begin{aligned}y\{e/x\} &= \begin{cases} e & \text{if } y = x \\ y & \text{otherwise} \end{cases} \\(e_1 e_2)\{e/x\} &= (e_1\{e/x\}) (e_2\{e/x\}) \\(\lambda y.e_1)\{e/x\} &= \lambda y.e_1\{e/x\} \quad \text{where } y \neq x\end{aligned}$$

Unfortunately this definition produces the wrong results when we substitute an expression with free variables under a  $\lambda$ . For example,

$$(\lambda y.x)\{y/x\} = (\lambda y.y)$$

To fix this problem, we need to revise our definition so that when we substitute under a  $\lambda$  we do not accidentally bind variables in the expression we are substituting. The following definition correctly implements *capture-avoiding substitution*:

$$\begin{aligned}y\{e/x\} &= \begin{cases} e & \text{if } y \neq x \\ y & \text{otherwise} \end{cases} \\(e_1 e_2)\{e/x\} &= (e_1\{e/x\}) (e_2\{e/x\}) \\(\lambda y.e_1)\{e/x\} &= \lambda y.(e_1\{e/x\}) \quad \text{where } y \neq x \text{ and } y \notin fv(e)\end{aligned}$$

Note that in the case for  $\lambda$ -abstractions, we require that the bound variable  $y$  be different from the variable  $x$  we are substituting for and that  $y$  not appear in the free variables of  $e$ , the expression we are substituting. Because we work up to  $\alpha$ -equivalence, we can always pick  $y$  to satisfy these side conditions. For example, to calculate  $(\lambda z.x z)\{(w y z)/x\}$  we first rewrite  $\lambda z.x z$  to  $\lambda u.x u$  and then apply the substitution, obtaining  $\lambda u.(w y z) u$  as the result.
