

Lecture 22

While Loops

Announcements for This Lecture

Assignments

- A6 due on **Wednesday**
 - First two should be done
 - Start Algorithm by weekend
 - **Next Week**: Partition/Update
- A7 will be last assignment
 - Will talk about next week
 - Posted on Wednesday
- There is lab next week
 - **No lab** week of Turkey Day

Prelim 2

- **TONIGHT**, 5:15 or 7:30
 - **K – Z** at 5:15pm
 - **A – J** at 7:30 pm
 - See website for room
 - Conflicts received e-mail
- Will have 4-5 questions
 - Might drop short answer
 - Similar to previous years
- Graded by the weekend

Recall: For Loops

```
# Print contents of seq
x = seq[0]
print(x)
x = seq[1]
print(x)
...
x = seq[len(seq)-1]
print(x)
```

The for-loop:

```
for x in seq:
    print(x)
```

- Key Concepts
 - **loop sequence:** `seq`
 - **loop variable:** `x`
 - **body:** `print(x)`
 - Also called **repetend**

Important Concept in CS: Doing Things Repeatedly

1. Process each item in a sequence

- Compute aggregate statistics for a sequence of numbers, such as the mean, median, standard deviation
- Send everyone in a Facebook group an appointment time

```
for x in sequence:  
    process x
```

2. Perform n trials or get n samples.

- A4: draw a triangle six times to make a snowflake
- Run a protein-folding simulation

```
for x in range(n):  
    do next thing
```

3. Do something an unknown number of times

- CUAUV team, vehicle keeps moving until reached its goal

????

Beyond Sequences: The **while**-loop

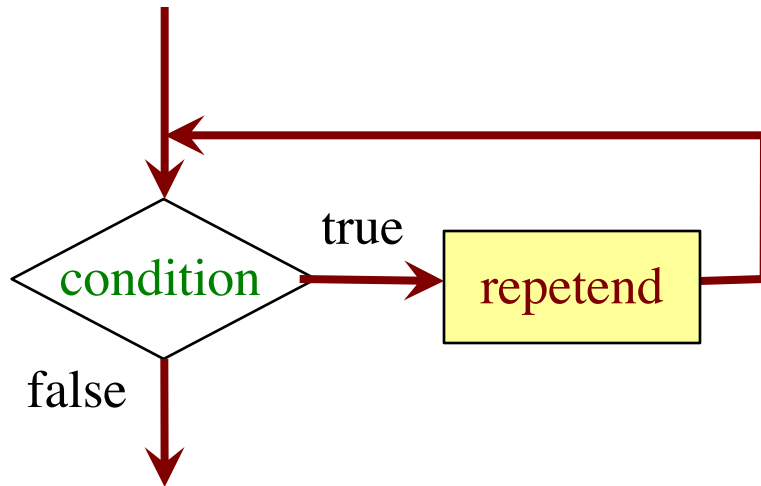

while *<condition>*:

statement 1

...

statement n

repetend or **body**

- Relationship to for-loop
 - Broader notion of “still stuff to do”
 - Must explicitly ensure condition becomes false
 - *You* explicitly manage what changes per iteration

While-Loops and Flow

```
print('Before while')
count = 0
i = 0
while i < 3:
    print('Start loop '+str(i))
    count = count + i
    i = i + 1
    print('End loop ')
print('After while')
```

Output:

```
Before while
Start loop 0
End loop
Start loop 1
End loop
Start loop 2
End loop
After while
```

while Versus for

```
# process range b..c-1  
for k in range(b,c)  
    process k
```

Must remember to increment

```
# process range b..c  
for k in range(b,c+1)  
    process k
```

```
# process range b..c-1  
k = b  
while k < c:  
    process k  
    k = k+1
```

```
# process range b..c  
k = b  
while k <= c:  
    process k  
    k = k+1
```

Range Notation

- $m..n$ is a range containing $n+1-m$ values
 - $2..5$ contains 2, 3, 4, 5. Contains $5+1 - 2 = 4$ values
 - $2..4$ contains 2, 3, 4. Contains $4+1 - 2 = 3$ values
 - $2..3$ contains 2, 3. Contains $3+1 - 2 = 2$ values
 - $2..2$ contains 2. Contains $2+1 - 2 = 1$ values
 - $2..1$ contains ???

What does $2..1$ contain?

A: nothing

B: 2,1

C: 1

D: 2

E: something else

Range Notation

- $m..n$ is a range containing $n+1-m$ values
 - $2..5$ contains 2, 3, 4, 5. Contains $5+1 - 2 = 4$ values
 - $2..4$ contains 2, 3, 4. Contains $4+1 - 2 = 3$ values
 - $2..3$ contains 2, 3. Contains $3+1 - 2 = 2$ values
 - $2..2$ contains 2. Contains $2+1 - 2 = 1$ values
 - $2..1$ contains ???
- The notation $m..n$, always implies that $m \leq n+1$
 - So you can assume that even if we do not say it
 - If $m = n+1$, the range has 0 values

while Versus for

```
# incr seq elements
```

```
for k in range(len(seq)):
```

```
    seq[k] = seq[k]+1
```

Makes a **range object**.

```
# incr seq elements
```

```
k = 0
```

```
while k < len(seq):
```

```
    seq[k] = seq[k]+1
```

```
    k = k+1
```

while is more flexible, but
requires more code to use

Patterns for Processing Integers

range a..b-1

`i = a`

while `i < b`:

 process integer i

`i = i + 1`

```
# store in count # of '/'s in String s
```

```
count = 0
```

```
i = 0
```

```
while i < len(s):
```

```
    if s[i] == '/':
```

```
        count = count + 1
```

```
    i = i + 1
```

```
# count is # of '/'s in s[0..s.length()-1]
```

range c..d

`i = c`

while `i <= d`:

 process integer i

`i = i + 1`

```
# Store in double var. v the sum
```

```
# 1/1 + 1/2 + ... + 1/n
```

```
v = 0; # call this 1/0 for today
```

```
i = 1
```

```
while i <= n:
```

```
    v = v + 1.0 / i
```

```
    i = i + 1
```

```
# v = 1/1 + 1/2 + ... + 1/n
```

while Versus for

```
# table of squares to N
seq = []
n = floor(sqrt(N)) + 1
for k in range(n):
    seq.append(k*k)
```

```
# table of squares to N
seq = []
k = 0
while k*k < N:
    seq.append(k*k)
    k = k+1
```

A for-loop requires that you know where to stop the loop **ahead of time**

A while loop can use complex expressions to check if the loop is done

while Versus for

Fibonacci numbers:

$$F_0 = 1$$

$$F_1 = 1$$

$$F_n = F_{n-1} + F_{n-2}$$

Table of n Fibonacci nums

```
fib = [1, 1]
```

```
for k in range(2,n):
```

```
    fib.append(fib[-1] + fib[-2])
```

Sometimes you do not use
the loop variable at all

Table of n Fibonacci nums

```
fib = [1, 1]
```

```
while len(fib) < n:
```

```
    fib.append(fib[-1] + fib[-2])
```

Do not need to have a loop
variable if you don't need one

Cases to Use **while**

Great for when you must **modify** the loop variable

```
# Remove all 3's from list t
```

```
i = 0
```

```
while i < len(t):
```

```
    # no 3's in t[0..i-1]
```

```
    if t[i] == 3:
```

```
        | del t[i]
```

```
    else:
```

```
        | i = i+1
```

```
# Remove all 3's from list t
```

```
while 3 in t:
```

```
    | t.remove(3)
```

Cases to Use **while**

Great for when you must **modify** the loop variable

```
# Remove all 3's from list t
```

```
i = 0
```

```
while i < len(t):
```

```
    # no 3's in t[0..i-1]
```

```
    if t[i] == 3:
```

```
        | del t[i]
```

```
    else:
```

```
        | i = i+1
```

Stopping point keeps changing.

```
# Remove all 3's from list t
```

```
while 3 in t:
```

```
    | t.remove(3)
```

The stopping condition is not a numerical counter this time. Simplifies code a lot.

Cases to Use while

- Want square root of c
 - Make poly $f(x) = x^2 - c$
 - Want root of the poly (x such that $f(x)$ is 0)
- Use **Newton's Method**
 - $x_0 = \text{GUESS}$ ($c/2??$)
 - $x_{n+1} = x_n - f(x_n)/f'(x_n)$
 $= x_n - (x_n x_n - c)/(2x_n)$
 $= x_n - x_n/2 + c/2x_n$
 $= x_n/2 + c/2x_n$
 - Stop when x_n good enough

```
def sqrt(c):
```

```
    """Return: square root of c  
    Uses Newton's method  
    Pre: c >= 0 (int or float)"""
```

```
    x = c/2
```

```
    # Check for convergence
```

```
    while abs(x*x - c) > 1e-6:
```

```
        # Get  $x_{n+1}$  from  $x_n$ 
```

```
        x = x / 2 + c / (2*x)
```

```
    return x
```

Recall Lab 9

Welcome to CS 1110 Blackjack.

Rules: Face cards are 10 points. Aces are 11 points.
All other cards are at face value.

Your hand:

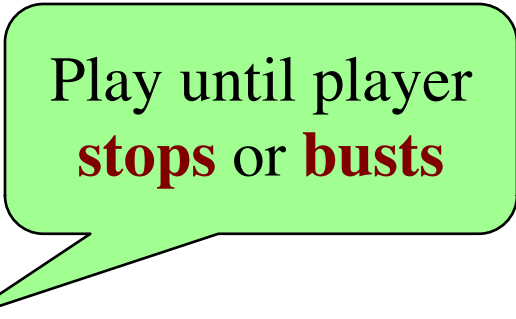

2 of Spades

10 of Clubs

Dealer's hand:

5 of Clubs

Type h for new card, s to stop:

Play until player
stops or **busts**

Recall Lab 9

Welcome to CS 1110 Blackjack.

Rules: Face cards are 10 points. Aces are 11 points.
All other cards are at face value.

Your hand:
2 of Spades
10 of Clubs

How do we design
this as a loop?

Dealer's hand:
5 of Clubs

Play until player
stops or **busts**

Type h for new card, s to stop:

Recall Lab 9

```
halted = False
```

```
while not game.playerBust() and not halted:
```

```
    # ri: input received from player
```

```
    ri = input('Type h for new card, s to stop: ')
```

```
    halted = (ri == 's')
```

```
if (ri == 'h'):
```

```
    game.playerHand.append(game.deck.pop(0))
```

```
    print('You drew the ' + str(game.playerHand[-1]) + '\n')
```

Recall Lab 9

```
halted = False
```

Explicit loop variable

```
while not game.playerBust() and not halted:
```

```
# ri: input received from player
```

```
ri = input('Type h for new card, s to stop: ')
```

```
halted = (ri == 's')
```

Set to False to
break the loop

```
if (ri == 'h'):
```

```
    game.playerHand.append(game.deck.pop(0))
```

```
    print('You drew the ' + str(game.playerHand[-1]) + '\n')
```

Recall Lab 9

```
halted = False
```

More than one way to stop

```
while not game.playerBust() and not halted:
```

```
    # ri: input received from player
```

```
    ri = input('Type h for new card, s to stop: ')
```

```
    halted = (ri == 's')
```

```
if (ri == 'h'):
```

```
    game.playerHand.append(game.deck.pop(0))
```

```
    print('You drew the ' + str(game.playerHand[-1]) + '\n')
```

Using while-loops Instead of for-loops

Advantages

- Better for **modifying data**
 - More natural than range
 - Works better with deletion
- Better for **convergent tasks**
 - Loop until calculation done
 - Exact steps are unknown
- Easier to **stop early**
 - Just set loop var to False

Disadvantages

- Performance is **slower**
 - Python optimizes for-loops
 - Cannot optimize while
- **Infinite loops** more likely
 - Easy to forget loop vars
 - Or get stop condition wrong
- **Debugging** is harder
 - Will see why in later lectures

Our Goal From Here: Sorting

Will see how to
do this with
while-loops
