

This lab concerns exception handling, the topic of the lecture on 7 April. This material will be covered on the final. Download file `Lab12.java` from the course web page. Put it in a new directory, open the file in DrJava, and compile.

Task 1. Get familiar with function `getKeyboard`. You will be using this function later. Read its specification and try it out by typing this into the Interactions pane.

```
c = Lab12.getKeyboard();
c.readLine()
```

When the box appears in the Interactions pane, type something into it and hit the return/enter key.

Task 2. Get familiar with checked exceptions. Study function `readKeyboardLine`; make sure you understand the specification and the function body.

Note the throws-clause `throws IOException` in the function header. *IO* stands for *input-output*, and an `IOException` is thrown whenever some sort of input-output error happens.

Delete the clause `throws IOException` from the header of function `readKeyboardLine` and try to compile. You get a syntax-error message, right? Read it. Then put the throws-clause back in the function header and compile.

As explained on pp. 323-325 of the text, Java expects that an exception that may be thrown in a method body either (1) be caught in that method body or (2) be mentioned in the throws clause of the method header, so that the user has a syntactic indication that the exception may be thrown.

All exceptions that may be thrown must be checked except for instances of `RuntimeException` (and its subclasses).

Do not actively be concerned about these throws clause. Instead, work as follows. Whenever you try to compile but Java says that a throws clause is needed, put it in.

Task 3. Complete function `readKeyboardInt`. From the spec of this function, you know that it is supposed to keep prompting the user for an integer, giving them a message when they type something different from an integer. For this purpose, use an infinite loop whose body is a try statement:

```
try {
    ...
} catch (decl. of an exception variable) {
    ...
}
```

where the following describes the try- and catch-blocks:

1. The try-block reads a line from the keyboard and returns the value of a suitable call on function `Integer.parseInt`. To help you out, the spec for `Integer.parseInt` is given to the right.

2. The catch-block catches any exception thrown by `Integer.parseInt` and prints (using `System.out.println`) a suitable message for the user. Note that the declaration of an exception variable is simply a declaration of the form “*type-or-class variable*”. In this case, the type-or-class is the class of the exception thrown by `Integer.parseInt`.

Task 4. Using exception handling for preconditions to aid in robust programming. Throughout this course, we have used the term *precondition* for a true-false statement that should be true when the method is called and it is the caller’s duty to ensure that it is true. Take a look at function `exp` in class `Lab12`. It has the precondition $c \geq 0$. In this case, if the user calls `exp` with $c < 0$, infinite recursion results.

From the API specification for `Integer.parseInt` (and then edited)

```
public static int parseInt
    (String s)
    throws NumberFormatException
```

Parse `s` as a signed decimal integer. The chars in `s` must be decimal digits, except that the first character may be an ASCII minus sign ‘-’ (`“\u002D”`) to indicate a negative value. Return the resulting integer value. Throw a `NumberFormatException` if `s` does not contain a parsable `int`.

Exception handling can be used to enable more robust programming. A robust program will prevent abnormal termination and unexpected actions —like this infinite loop. Robust programming requires that invalid inputs, for example invalid arguments of a call, be handled in a reasonable way. In the case of function `exp`, the function itself doesn't know how to handle the error $c < 0$, but it can throw an exception so that the user can handle it.

Change the specification of function `exp` so that it says that it throws an exception if $c < 0$ —indicating which one is thrown. You can choose an appropriate one from the list given to the right; these (and many more!) are defined in the Java API package. Then, change the function itself to throw that exception, with a suitable message in the exception, if $c < 0$.

Some Java Exception classes

```
ApplicationException
ArithmeticException
ArrayStoreException
FileNotFoundException
IndexOutOfBoundsException
IllegalArgumentException
IllegalStateException
InvalidOperationException
InvalidParameterException
```

Make sure function `exp` works correctly by using the function call `Lab12.exp(1, -3)` in the interactions pane. Write down what happens here:

Task 5. Writing a throwable class definition. Define subclass `MyException` of class `Exception`. It needs two constructors; one with no parameters and one with one `String` parameter, which is the detail message. Please be sure to write specifications for the constructors.

Task 6. Writing a procedure to use what you have done. Suppose $0 < x < 1$. How fast does x^i approach 0 as i increases? Write function `approach` to find out —its specification is given in class `Lab12`.

Note that for x satisfying $0 < x < 1$, $x^0 = 1$, so that there is some positive integer i that satisfies the spec.

After testing your function to be sure that it works, try it in the interactions pane with various values of x , like .01, .99, .999, .9999, .99999 —and of course 0, -2, 1, and 2 to be sure that throwing an exception works properly. When done, you might want to change the spec and function body to throw an `IllegalArgumentException` instead of a `MyException`. In this case, it makes more sense to use it. You can then delete the “**throws** `MyException`” clause from the method header.

Please show what you have done to your TA or a consultant —let them look at your computer monitor to make sure you wrote the methods correctly. If you don't finish the week it is supposed to be done, bring a listing of class `Lab12` the next week so that the TA can see that you have done things correctly.
