

## We Write Programs to Do Things

- Functions are the **key doers**

Function Call	Function Definition
<ul style="list-style-type: none"> <li>Command to <b>do</b> the function</li> </ul> <pre>greet('Walker')</pre> <p>argument to assign to n</p>	<ul style="list-style-type: none"> <li>Defines what function <b>does</b></li> </ul> <pre>def greet(n):     print 'Hello '+n+'!'</pre> <p>Function Header</p> <p>declaration of parameter n</p> <p>Function Body (indented)</p>

- Parameter:** variable that is listed within the parentheses of a method header.
- Argument:** a value to assign to the method parameter when it is called

9/7/12 1

## Anatomy of a Function Definition

```
def greet(n):
    """Prints a greeting to the name n
    Precondition: n is a string
    representing a person's name"""
    print 'Hello '+n+'!'
    print 'How are you?'
```

name      parameters

Function Header

Docstring Specification

Statements to execute when called

The vertical line indicates indentation

Use vertical lines when you write Python on exams so we can see indentation

2/2/12 Classes 2

## Procedures vs. Fruitful Functions

Procedures	Fruitful Functions
<ul style="list-style-type: none"> <li>Functions that <b>do</b> something</li> <li>Call them as a <b>statement</b></li> <li>Example: <code>greet('Walker')</code></li> </ul>	<ul style="list-style-type: none"> <li>Functions that give a <b>value</b></li> <li>Call them in an <b>expression</b></li> <li>Example: <code>x = round(2.56,1)</code></li> </ul>

**Historical Aside**

- Historically “function” = “fruitful function”
- But now we use “function” to refer to both

2/2/12 Classes 3

## The return Statement

- Fruitful functions require a **return statement**
- Format:** `return <expression>`
  - Provides value when call is used in an expression
  - Also stops executing the function!
  - Any statements after a **return** are ignored
- Example:** temperature converter function

```
def to_centiGrade(x):
    """Returns: x converted to centigrade"""
    return 5*(x-32)/9.0
```

2/2/12 Classes 4

## Aside: Constants

- Modules often have variables outside a function
  - We call these global variables
  - Accessible once you import the module
- Global variables should be **constants**
  - Variables that never, ever change
  - Mnemonic representation of important value
  - Example:** `math.pi`, `math.e` in `math`
- In this class, constant names are **capitalized!**
  - So we can tell them apart from non-constants

2/2/12 Classes 5

## Module Example: Temperature Converter

```
# temperature.py
"""Conversion functions between fahrenheit and centigrade"""

# Functions
def to_centiGrade(x):
    """Returns: x converted to centigrade"""
    return 5*(x-32)/9.0

def to_fahrenheit(x):
    """Returns: x converted to fahrenheit"""
    return 9*x/5.0+32

# Constants
FREEZING_C = 0.0 # temp. water freezes
```

**Style Guideline:**  
Two blank lines between function definitions

2/2/12 Classes 6

## How Do Functions Work?

Draw template on a piece of paper

- **Function Frame:** Representation of a function call
- A **conceptual model** of Python

Draw parameters as variables (named boxes)

Number of statement in the function body to execute next  
Starts with 1

function name    instruction counter

parameters

local variables (later in lecture)

9/10/12                      Methods & Constructors                      7

## Example: to\_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
  - Look for variables in the frame
  - If not there, look for global variables with that name
4. Erase the frame for the call

Initial call frame (before exec body)

to\_centigrade

x 50.0

1

next line to execute

```
def to_centigrade(x):
1 | return 5*(x-32)/9.0
```

9/10/12                      Methods & Constructors                      8

## Example: to\_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
  - Look for variables in the frame
  - If not there, look for global variables with that name
4. Erase the frame for the call

Executing the return statement

to\_centigrade

x 50.0

1

The return terminates; no next line to execute

```
def to_centigrade(x):
1 | return 5*(x-32)/9.0
```

9/10/12                      Methods & Constructors                      9

## Example: to\_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
  - Look for variables in the frame
  - If not there, look for global variables with that name
4. Erase the frame for the call

ERASE WHOLE FRAME

But don't actually erase on an exam

```
def to_centigrade(x):
1 | return 5*(x-32)/9.0
```

9/10/12                      Methods & Constructors                      10

## Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):
    """Swap vars a & b"""
1 | tmp = a
2 | a = b
3 | b = tmp
```

>>> a = 1  
>>> b = 2  
>>> swap(a,b)

Global Variables

a 1    b 2

Call Frame

swap

a 2    b 1

tmp 1

2/2/12                      Classes                      11

## Example with Objects

- Mutable objects can be altered in a function call
  - Object vars hold names!
  - Folder accessed by both global var & parameter
- **Example:**

```
def incr_x(q):
1 | q.x = q.x + 1
```

>>> p = Point()  
>>> incr\_x(p)

Global Variable

43001122    p 43001122

x 1.0    Point

...

Call Frame

incr\_x

q 43001122
