

Lecture 5

Visualizing Functions

Announcements For This Lecture

Readings

- See link on website:
 - Docstrings in Python
 - Material is not in Text

Today's Lab

- Practice today's lecture
- **Highly recommend doing optional part**

Assignment 1

- Posted on web page
 - Due Wed, Sep. 18th
 - Revise until correct
- Can work in pairs
 - One submission for pair
 - Link up on Piazza
- **Consultants can help**

One-on-One Sessions

- Starting tomorrow: **1/2-hour one-on-one sessions**
 - Bring computer to work with instructor, TA or consultant
 - Hands on, dedicated help with Lab 2 and/or Lab 3
 - To prepare for assignment, **not for help on assignment**
- **Limited availability: we cannot get to everyone**
 - Students with experience or confidence should hold back
- Sign up online in CMS: first come, first served
 - Choose assignment One-on-One
 - Pick a time that works for you; will add slots as possible
 - Can sign up starting at 1pm **TODAY**

Anatomy of a Specification

```
def greet(n):
```

```
    """Prints a greeting to the name n
```

```
    Greeting has format 'Hello <n>!'
    Followed by a conversation starter.
```

```
    Precondition: n is a string
    representing a person's name"""
```

```
    print 'Hello '+n+'!'
    print 'How are you?'
```

One line description,
followed by blank line

More detail about the
function. It may be
many paragraphs.

Precondition specifies
assumptions we make
about the arguments

Anatomy of a Specification

```
def to_centiGrade(x):
```

```
    """Returns: x converted to centigrade
```

```
    Value returned has type float.
```

```
    Precondition: x is a float measuring
    temperature in fahrenheit"""
```

```
return 5*(x-32)/9.0
```

“Returns” indicates a fruitful function

More detail about the function. It may be many paragraphs.

Precondition specifies assumptions we make about the arguments

Preconditions

- Precondition is a **promise**
 - If precondition is true, the function works
 - If precondition is false, no guarantees at all
- Get **software bugs** when
 - Function precondition is not documented properly
 - Function is used in ways that violates precondition

```
>>> to_centrigrade(32)
```

```
0.0
```

```
>>> to_centrigrade(212)
```

```
100.0
```

```
>>> to_centrigrade('32')
```

```
Traceback (most recent call last):
```

```
File "<stdin>", line 1, in <module>
```

```
File "temperature.py", line 19 ...
```

```
TypeError: unsupported operand type(s)  
for -: 'str' and 'int'
```

Precondition violated

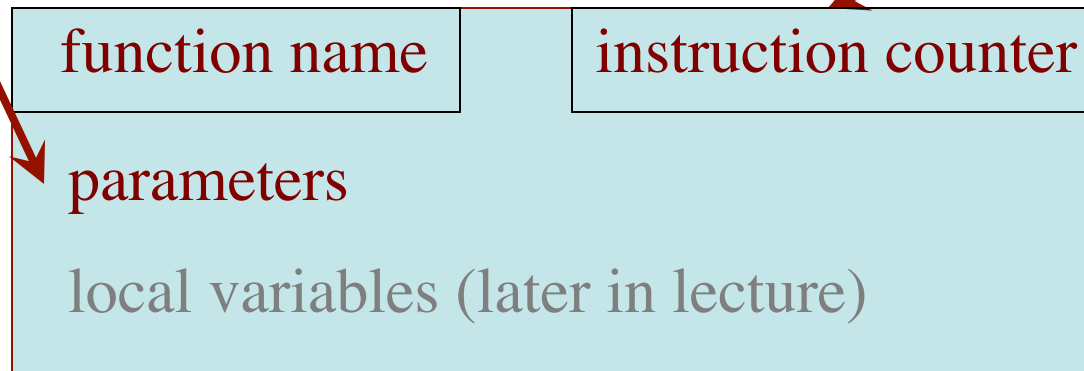

How Do Functions Work?

Draw template on
a piece of paper

- **Function Frame:** Representation of function call
- A **conceptual model** of Python

Draw parameters
as variables
(named boxes)

- Number of statement in the
function body to execute next
- **Starts with 1**

Text (Section 3.10) vs. Class

Textbook

to_centigrade

$x \rightarrow 50.0$

This Class

to_centigrade

1

x 50.0

Definition:

```
def to_centigrade(x):  
    | return 5*(x-32)/9.0
```

Call: to_centigrade(50.0)

Example: to_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
 - Look for variables in the frame
 - If not there, look for global variables with that name
4. Erase the frame for the call

Initial call frame
(before exec body)

next line to execute

```
1 def to_centigrade(x):  
    | return 5*(x-32)/9.0
```

Example: to_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
 - Look for variables in the frame
 - If not there, look for global variables with that name
4. Erase the frame for the call

```
1 def to_centigrade(x):  
    | return 5*(x-32)/9.0
```

Executing the
return statement

Return statement creates a
special variable for result

Example: to_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
 - Look for variables in the frame
 - If not there, look for global variables with that name
4. Erase the frame for the call

```
1 def to_centigrade(x):  
  | return 5*(x-32)/9.0
```

Executing the
return statement

The return terminates;
no next line to execute

Example: to_centigrade(50.0)

1. Draw a frame for the call
2. Assign the argument value to the parameter (in frame)
3. Execute the function body
 - Look for variables in the frame
 - If not there, look for global variables with that name
4. Erase the frame for the call

ERASE WHOLE FRAME

```
1 def to_centigrade(x):  
  | return 5*(x-32)/9.0
```

But don't actually
erase on an exam

Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):  
    """Swap vars a & b"""  
1   tmp = a  
2   a = b  
3   b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Variables

a **1** b **2**

Call Frame

Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):  
    """Swap vars a & b"""  
1   tmp = a  
2   a = b  
3   b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Variables

a **1** b **2**

Call Frame

Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):  
    """Swap vars a & b"""  
1   tmp = a  
2   a = b  
3   b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Variables

a **1** b **2**

Call Frame

Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):  
    """Swap vars a & b"""  
1   tmp = a  
2   a = b  
3   b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Variables

a 1 b 2

Call Frame

Call Frames vs. Global Variables

- This does not work:

```
def swap(a,b):  
    """Swap vars a & b"""  
1   tmp = a  
2   a = b  
3   b = tmp
```

```
>>> a = 1
```

```
>>> b = 2
```

```
>>> swap(a,b)
```

Global Variables

a **1** b **2**

Call Frame

Visualizing Frames: The Python Tutor

```
→ 1 def max(x,y):  
  2     if x > y:  
  3         return x  
  4     return y  
  5  
  6 a = 1  
  7 b = 2  
→ 8 max(a,b)
```

Visualizing Frames: The Python Tutor

Limitations of the Python Tutor

- The Python Tutor is extremely useful
 - You can see exactly what Python is doing
 - You could use it to find errors in your code!
- However, the Python tutor is very *limited*
 - You can only import the most basic modules
 - You cannot import user-defined modules
- We need some other way to search for errors
 - This is the motivation for **code testing**

Limitations of the Python Tutor

- The Python Tutor is extremely useful
 - You can run code
 - You can see the state of the program
- However, the Python tutor is very *limited*
 - You can only import the most basic modules
 - You cannot import user-defined modules
- We need some other way to search for errors
 - This is the motivation for **code testing**

Many professional software development tools do this too.

Test Cases: Finding Errors

- **Bug:** Error in a program. (Always expect them!)
- **Debugging:** Process of finding bugs and removing them.
- **Testing:** Process of analyzing, running program, looking for bugs.
- **Test case:** A set of input values, together with the expected output.

Get in the habit of writing test cases for a function from the function's specification —even *before* writing the function's body.

```
def number_vowels(w):  
    """Returns: number of vowels in word w.  
  
    Precondition: w string w/ at least one letter and only letters"""  
    pass # nothing here yet!
```

Test Cases: Finding Errors

- **Bug:** Error in a program. (Always
- **Debugging:** Process of finding bug
- **Testing:** Process of analyzing, run
- **Test case:** A set of input values, to

Get in the habit of writing test case function's specification —even *before*

Some Test Cases

- `number_vowels('Bob')`
Answer should be 1
- `number_vowels('Aeiuo')`
Answer should be 5
- `number_vowels('Grrr')`
Answer should be 0

```
def number_vowels(w):
```

```
    """Returns: number of vowels in word w.
```

```
    Precondition: w string w/ at least one letter and only letters"""
```

```
    pass # nothing here yet!
```

Representative Tests

- Cannot test all inputs
 - “Infinite” possibilities
- Limit ourselves to tests that are **representative**
 - Each test is a significantly different input
 - Every possible input is similar to one chosen
- An art, not a science
 - If easy, never have bugs
 - Learn with much practice

Representative Tests for number_vowels(w)

- Word with just one vowel
 - For each possible vowel!
- Word with multiple vowels
 - Of the same vowel
 - Of different vowels
- Word with only vowels
- Word with no vowels

Running Example

- The following function has a bug:

```
def last_name_first(n):  
    """Returns: copy of <n> but in the form <last-name>, <first-name>  
  
    Precondition: <n> is in the form <first-name> <last-name>  
    with one or more blanks between the two names"""  
    end_first = n.find(' ')  
    first = n[:end_first]  
    last = n[end_first+1:]  
    return last+', '+first
```

Look at precondition
when choosing tests

- Representative Tests:
 - `last_name_first('Walker White')` give 'White, Walker'
 - `last_name_first('Walker White')` gives 'White, Walker'

Unit Test: A Special Kind of Module

- A unit test is a module that tests another module
 - It **imports the other module** (so it can access it)
 - It **imports the `cornelltest` module** (for testing)
 - It **defines one or more test procedures**
 - Evaluate the function(s) on the test cases
 - Compare the result to the expected value
 - It has special code that **calls the test procedures**
- The test procedures use the `cornelltest` function

```
def assert_equals(expected,received):  
    """Quit program if expected and received differ"""
```

Modules vs. Scripts

Module

- Provides functions, constants
 - **Example:** temperature.py
- import it into Python
 - In interactive shell...
 - or other module
- All code is either
 - In a function definition, or
 - A variable assignment

Script

- Behaves like an application
 - **Example:** helloApp.py
- Run it from command line
 - python helloApp.y
 - No interactive shell
 - import acts “weird”
- Commands *outside* functions
 - Does each one in order

Combining Modules and Scripts

- Scripts often have functions in them
 - Can we import them without “running” script?
 - Want to separate script part from module part
- New feature: **if** `__name__ == '__main__':`
 - Put all “script code” underneath this line
 - Also, indent all the code underneath
 - Prevents code from running if imported
 - **Example:** `bettertemp.py`

Modules/Scripts in this Course

- Our modules consist of
 - Function definitions
 - “Constants” (global vars)
 - **Optional** script code to call/test the functions
- All **statements** must
 - be inside of a function **or**
 - assign a constant **or**
 - be in the application code
- **import** should only pull in definitions, not app code

```
# temperature.py
...
# Functions
def to_centigrade(x):
    | """Returns: x converted to C"""
...
# Constants
FREEZING_C = 0.0 # temp. water freezes
...
# Application code
if __name__ == '__main__':
    | assert_floats_equal(0.0,to_centigrade(32.0))
    | assert_floats_equal(100,to_centigrade(212))
    | assert_floats_equal(32.0,to_fahrenheit(0.0))
    | assert_floats_equal(212.0,to_fahrenheit(100.0))
```

Testing last_name_first(n)

```
# test procedure
```

```
def test_last_name_first():
```

```
    """Test procedure for last_name_first(n)"""
```

```
    cornelltest.assert_equals('White, Walker',  
                              last_name_first('Walker White'))
```

```
    cornelltest.assert_equals('White, Walker',  
                              last_name_first('Walker White'))
```

Expected is the
literal value.

Received is the
expression.

Quits Python
if not equal

```
# Application code
```

```
if __name__ == '__main__':
```

```
    test_last_name_first()
```

```
    print 'Module name is working correctly'
```

Message will print
out only if no errors.

Testing last_name_first(n)

```
# test procedure
```

```
def test_last_name_first():
```

```
    """Test procedure for last_name_first(n)"""
```

```
    cornelltest.assert_equals('White, Walker',  
                               last_name_first('Walker White'))
```

```
    cornelltest.assert_equals('White, Walker',  
                               last_name_first('Walker White'))
```

Expressions inside
of () can be split
over several lines.

Quits Python
if not equal

```
# Application code
```

```
if __name__ == '__main__':
```

```
    test_last_name_first()
```

```
    print 'Module name is working correctly'
```

Message will print
out only if no errors.

Finding the Error

- Unit tests cannot find the source of an error
- Idea: “Visualize” the program with print statements

```
def last_name_first(n):
```

```
    """Returns: copy of <n> in form <last>, <first>"""
```

```
    end_first = n.find(' ')
```

```
    print end_first
```

```
    first = n[:end_first]
```

```
    print 'first is '+ `first`
```

```
    last = n[end_first+1:]
```

```
    print 'last is '+ `last`
```

```
    return last+', '+first
```

Print variable after each assignment

Optional: Annotate value to make it easier to identify

Types of Testing

Black Box Testing

- Function is “opaque”
 - Test looks at what it does
 - **Fruitful**: what it returns
 - **Procedure**: what changes
- **Example**: Unit tests
- **Problems**:
 - Are the tests everything?
 - What caused the error?

White Box Testing

- Function is “transparent”
 - Tests/debugging takes place inside of function
 - Focuses on where error is
- **Example**: Use of print
- **Problems**:
 - Much harder to do
 - Must remove when done
