

Announcements for This Lecture

Assignment & Lab

- A6 is not graded yet
 - Done by end of classes
- A7 due **Wed, Dec. 10**
 - Wednesday after classes
 - Keep on top of milestones
 - Is your paddle moving?
- Lab Today: Office Hours
 - Get help on A7 paddle
 - Anyone can go to any lab

Next Week

- Last Week of Class!
 - Finish sorting algorithms
 - Special final lecture
- Lab held, but is optional
 - More invariant practice
 - Also use lab time on A7
- Details about the exam
 - Multiple review sessions

Recall: Horizontal Notation

Example of an assertion about an sequence b. It asserts that:

- $b[0..k-1]$ is sorted (i.e. its values are in ascending order)
- Everything in $b[0..k-1]$ is \leq everything in $b[k..len(b)-1]$

Given index h of the first element of a segment and index k of the element that follows that segment, the number of values in the segment is $k - h$.

$b[h .. k - 1]$ has $k - h$ elements in it. $(h+1) - h = 1$

Partition Algorithm

- Given a sequence $b[h..k]$ with some value x in $b[h]$:

- Swap elements of $b[h..k]$ and store in j to truthify post:

- Agrees with precondition when $i = h, j = k+1$
- Agrees with postcondition when $j = i+1$

Partition Algorithm Implementation

```
def partition(b, h, k):
    """Partition list b[h..k] around a pivot x = b[h]"""
    i = h; j = k+1; x = b[h]
    # invariant: b[h..i-1] < x, b[i] = x, b[j..k] >= x
    while i < j-1:
        if b[i+1] >= x:
            # Move to end of block.
            _swap(b,i+1,j-1)
            j = j - 1
        else: # b[i+1] < x
            _swap(b,i+1)
            i = i + 1
    # post: b[h..i-1] < x, b[i] is x, and b[i+1..k] >= x
    return i
```

Partition Algorithm Implementation

```
def partition(b, h, k):
    """Partition list b[h..k] around a pivot x = b[h]"""
    i = h; j = k+1; x = b[h]
    # invariant: b[h..i-1] < x, b[i] = x, b[j..k] >= x
    while i < j-1:
        if b[i+1] >= x:
            # Move to end of block.
            _swap(b,i+1,j-1)
            j = j - 1
        else: # b[i+1] < x
            _swap(b,i+1)
            i = i + 1
    # post: b[h..i-1] < x, b[i] is x, and b[i+1..k] >= x
    return i
```

Dutch National Flag Variant

- Sequence of integer values
 - 'red' = negatives, 'white' = 0, 'blues' = positive
 - Only rearrange part of the list, not all

pre: $t = h,$
 $i = k+1,$
 $j = k$
post: $t = i$

Dutch National Flag Algorithm

```
def dnf(b, h, k):
    """Returns: partition points as a tuple (i,j)"""
    t = h; i = k+1; j = k;
    # inv: b[h..t-1] < 0, b[t..i-1] ?, b[i..j] = 0, b[j+1..k] > 0
    while t < i:
        if b[t-1] < 0:
            swap(b,i,t)
            t = t+1
        elif b[t-1] == 0:
            i = i-1
        else:
            swap(b,i-1,j)
            i = i-1; j = j-1
    # post: b[h..i-1] < 0, b[i..j] = 0, b[j+1..k] > 0
    return (i, j)
```

	< 0	?	= 0	> 0
h	t		i	j

Linear Search

- Vague:** Find first occurrence of v in b[h..k-1].
- Better:** Store an integer in i to truthify result condition post:
 - v is not in b[h..i-1]
 - i = k OR v = b[i]

pre: b [h...k] ?

post: b [h...i] k
 [v not here | v | ?]

OR

post: b [h...k] i
 [v not here]

Linear Search

pre: b [h...k] ?

post: b [h...i] k
 [v not here | v | ?]

OR

post: b [h...k] i
 [v not here]

inv: b [h...i] k
 [v not here | ?]

Linear Search

```
def linear_search(b,c,h):
    """Returns: first occurrence of c in b[h..k]"""
    # Store in i the index of the first c in b[h..k]
    i = h
    # invariant: c is not in b[0..i-1]
    while i < len(b) and b[i] != c:
        i = i + 1
    # post: c is not in b[h..i-1]
    # i >= len(b) or b[i] == c
    return i if i < len(b) else -1
```

Analyzing the Loop

1. Does the initialization make **inv** true?
2. Is **post** true when **inv** is true and **condition** is false?
3. Does the repetend make progress?
4. Does the repetend keep the invariant **inv** true?

Binary Search

- Vague:** Look for v in **sorted** sequence segment b[h..k].
- Better:**
 - Precondition:** b[h..k-1] is sorted (in ascending order).
 - Postcondition:** b[h..i] <= v and v < b[i+1..k-1]
- Below, the array is in non-descending order:

pre: b [h...k] ?

post: b [h...i] k
 [<= v | > v]

inv: b [h...i] j k
 [< v | ? | > v]

Called **binary search** because each iteration of the loop cuts the array segment still to be processed in half
