This lab gives you experience with writing recursive functions. All of the functions in this lab will either be recursive functions on sequences (e.g. strings or lists), or recursive functions on integers, just as we saw in class. They are also the right length for questions on Prelim 2.

This is a fairly important lab, but it is longer than normal. We will have a shorter lab next week to make up for it. It will help a lot with Prelim 2 if you finish this lab.

Lab Materials. We have created several Python files for this lab. You can download all of them from the Labs section of the course web page.

http://www.cs.cornell.edu/courses/cs1110/2016fa/labs

When you are done, you should have the following two files.

- lab08.py (a module with stubs that must be completed)
- test08.py (a completed test script).

Alternatively, you can get all of the files bundled in a single ZIP file called lab08.zip from the Labs section of the course web page.

Getting Credit for the Lab. Once again, you have a choice between getting credit through the online system or your instructor. The online lab is available at the web page

http://www.cs.cornell.edu/courses/cs1110/2016fa/labs/lab08/

By now you should have a good idea of which version you are more comfortable with. Once again this lab involves quite a bit of coding, so you may have trouble finishing it during lab time. For that reason, you might want to complete it using the online system.

The online system is fairly robust for this assignment. However, you should only type your answers into the online system after you have implemented them in lab08.py. We have provided you a completed test script with test08.py to check your answers before submitting them.

1. Recursive Functions

Most of the recursive functions in this lab are designed to be solved with the divide-and-conquer process. When you write your functions, you should break the solution down as follows:

Handle small data directly. The base case involves the “smallest” parameter values, for which the result can be given easily, without the need for recursive calls. For a function that works on a sequence (e.g. either a string or a list), the base case is usually a sequence of length 0 (or both length 0 and 1). If the data is a natural number, then small values are 0 and 1.

Course authors: D. Gries, L. Lee, S. Marschner, W. White
**Break the data into two parts.** For recursion to work, you must make the data “smaller.” The recursive calls make the data smaller and smaller, until it gets small enough to be handled directly. For sequences, you make the data smaller via slicing. For natural numbers, you make the value $n$ smaller by breaking it into two numbers $a$ and $b$ such that either $a+b$ or $a*b$ is $n$.

When you break the data into the two parts, you will need to call the function recursively on each half. As we saw in class, sometimes one of the halves is so small that we can compute the answer directly and do not need to use recursion on that half.

**Combine the answer.** Once you have the recursive answer for each half, you need to combine the answers together to get the answer on the entire data. Many times this is as simple as adding the answers together. However, as we saw in class, some functions require more complicated means of combination. Read the specification carefully to figure out what to do.

2. **Lab Activities**

In this lab, you are to implement the first four functions from the module `lab08.py`, specified below. All implementations must be recursive, using divide-and-conquer.

```python
def numberof(thelist,v):
    """Returns: number of times v occurs in thelist.
    Precondition: thelist is a list of ints, v is an int"
"
def replace(thelist,a,b):
    """Returns: a COPY of thelist but with all occurrences of a replaced by b.
    Example: replace([1,2,3,1], 1, 4) = [4,2,3,4].
    Precondition: thelist is a list of ints, a and b are ints"
"
def remove_dups(thelist):
    """Returns: a COPY of thelist with adjacent duplicates removed.
    Example: for thelist = [1,2,2,3,3,3,4,5,1,1,1], the answer is [1,2,3,4,1]
    Precondition: thelist is a list of ints"
"
def oddsevens(thelist):
    """Returns: copy of the list with odds at front, evens in the back.
    Odd numbers are in the same order as thelist. Evens are reversed.
    Example: oddsevens([3,4,5,6]) returns [3,5,6,4]
    oddsevens([2,3,4,5,6]) returns [3,5,6,4,2]
    oddsevens([1,2,3,4,5,6]) returns [1,3,5,6,4,2]
    Precondition: thelist is a list of ints (may be empty)"
"
```

Even though we only ask you to work on the first four functions in module `lab08.py` in this lab, you will get greater fluency in recursion if you do them all. Of the course of the next month, take some time to work on the remaining functions and test them. You should particularly try some of the integer recursive functions that appear later in `lab08.py`.
