

## Lecture 20

# **Subclasses & Inheritance**

# Announcements for Today

---

## Reading

---

- Today: Chapter 18
- Online reading for Thursday

- **Prelim, Nov 9<sup>th</sup> 7:30-9:00**
  - Material up to Thursday
  - Review posted on Thursday
  - Recursion + Loops + Classes
- **S/U Students are exempt**
- **Conflict with Prelim time?**
  - Prelim 2 Conflict on CMS
  - Submit by Thursday

## Assignments

---

- A4 graded by end of week
  - Survey is still open
- A5 was posted Thursday
  - Shorter written assignment
  - Due Thursday at Midnight
- A6 was posted Saturday
  - Due a **week after** prelim
  - Designed to take two weeks
  - Finish Task 3 before exam

# An Application

---

- **Goal:** Presentation program (e.g. PowerPoint)
- **Problem:** There are many types of content
  - **Examples:** text box, rectangle, image, etc.
  - Have to write code to display each one
- **Solution:** Use object oriented features
  - Define class for every type of content
  - Make sure each has a draw method:

```
for x in slide[i].contents:  
    x.draw(window)
```

# Sharing Work

---

- These classes will have a lot in common
  - Drawing handles for selection
  - Background and foreground color
  - Current size and position
  - And more (see the formatting bar in PowerPoint)
- **Result:** A lot of repetitive code
- **Solution:** Create one class with shared code
  - All content are *subclasses* of the *parent* class

Abbreviate  
as SC to right

# Defining a Subclass

```
class SlideContent(object):  
    """Any object on a slide."""  
    def __init__(self, x, y, w, h): ...  
    def draw_frame(self): ...  
    def select(self): ...
```

Superclass  
Parent class  
Base class

SlideContent

Subclass  
Child class  
Derived class

TextBox

Image

```
class TextBox(SlideContent):  
    """An object containing text."""  
    def __init__(self, x, y, text): ...  
    def draw(self): ...
```

SC

```
__init__(self,x,y,w,h)  
draw_frame(self)  
select(self)
```

```
class Image(SlideContent):  
    """An image."""  
    def __init__(self, x, y, image_file): ...  
    def draw(self): ...
```

TextBox(SC)

```
__init__(self,x,y,text)  
draw(self)
```

Image(SC)

```
__init__(self,x,y,img_f)  
draw(self)
```

# Class Definition: Revisited

---

**class** *<name>*(*<superclass>*):

"""Class specification"""

getters and setters

initializer (`__init__`)

definition of operators

definition of methods

anything else

Class type to extend  
(may need module name)

- Every class must extend *something*
- Previous classes all extended *object*

# object and the Subclass Hierarchy

- Subclassing creates a **hierarchy** of classes
  - Each class has its own super class or parent
  - Until object at the “top”
- object has many features
  - Special built-in fields: `__class__`, `__dict__`
  - Default operators: `__str__`, `__repr__`

## Kivy Example

object

kivy.uix.widge.WidgetBase

kivy.uix.widget.Widget

kivy.uix.label.Label

kivy.uix.button Button

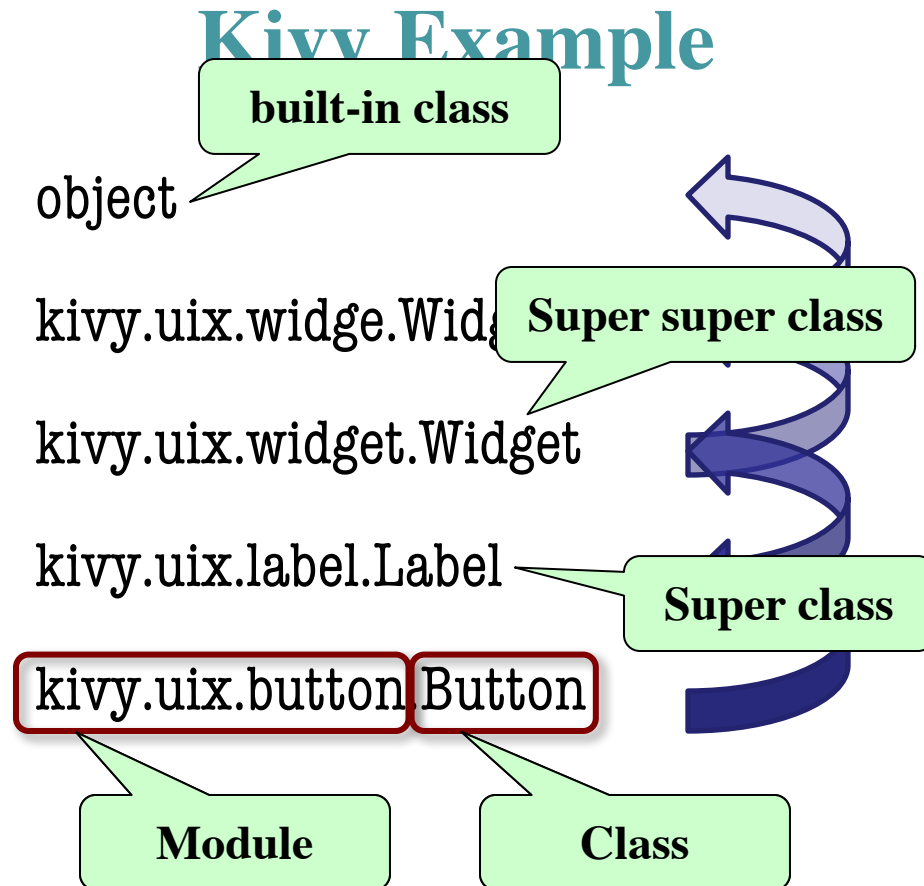

Module

Class

# object and the Subclass Hierarchy

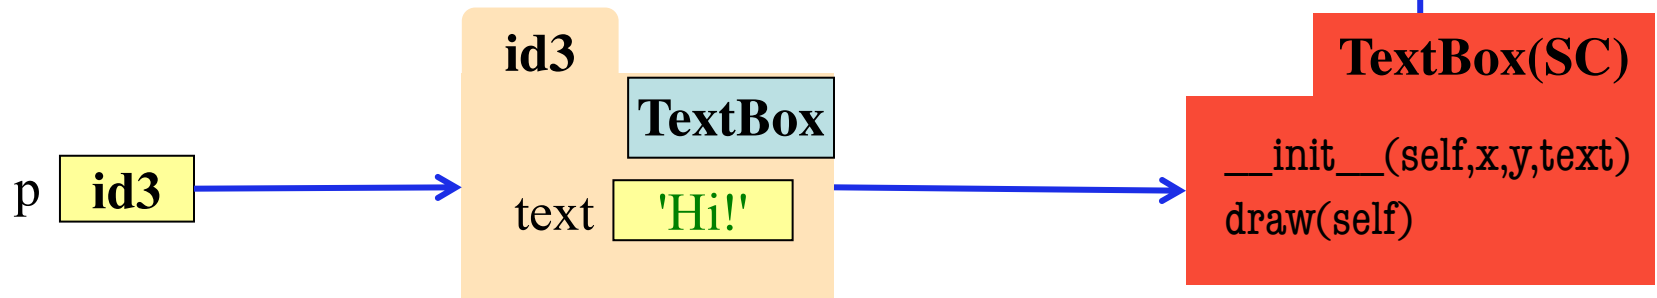

- Subclassing creates a **hierarchy** of classes
  - Each class has its own super class or parent
  - Until object at the “top”
- object has many features
  - Special built-in fields: `__class__`, `__dict__`
  - Default operators: `__str__`, `__repr__`

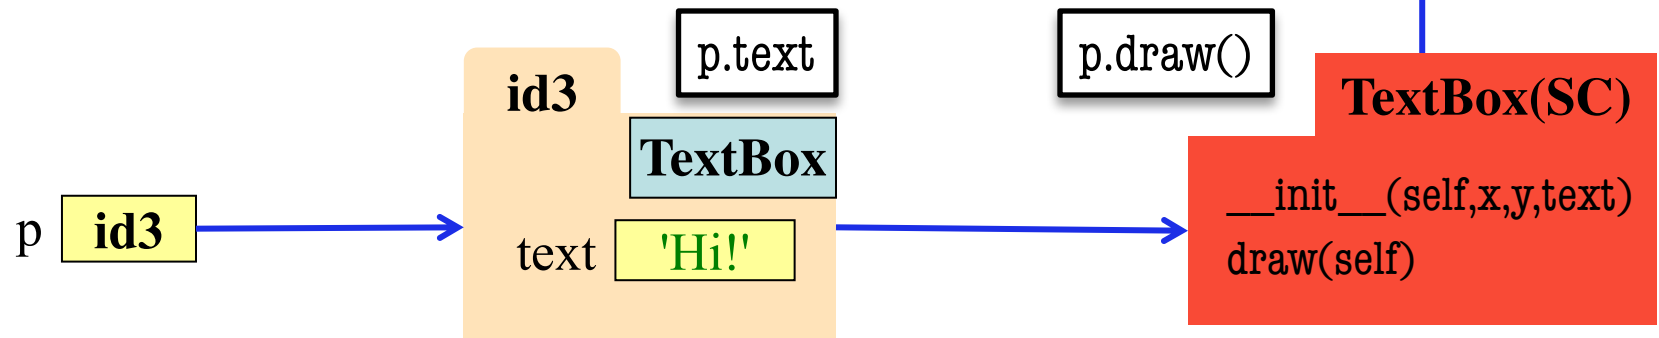

# Name Resolution Revisited

- To look up attribute/method name
  1. Look first in instance (object folder)
  2. Then look in the class (folder)
- Subclasses add two more rules:
  3. Look in the superclass
  4. Repeat 3. until reach object

# Name Resolution Revisited

- To look up attribute/method name
  1. Look first in instance (object folder)
  2. Then look in the class (folder)
- Subclasses add two more rules:
  3. Look in the superclass
  4. Repeat 3. until reach object

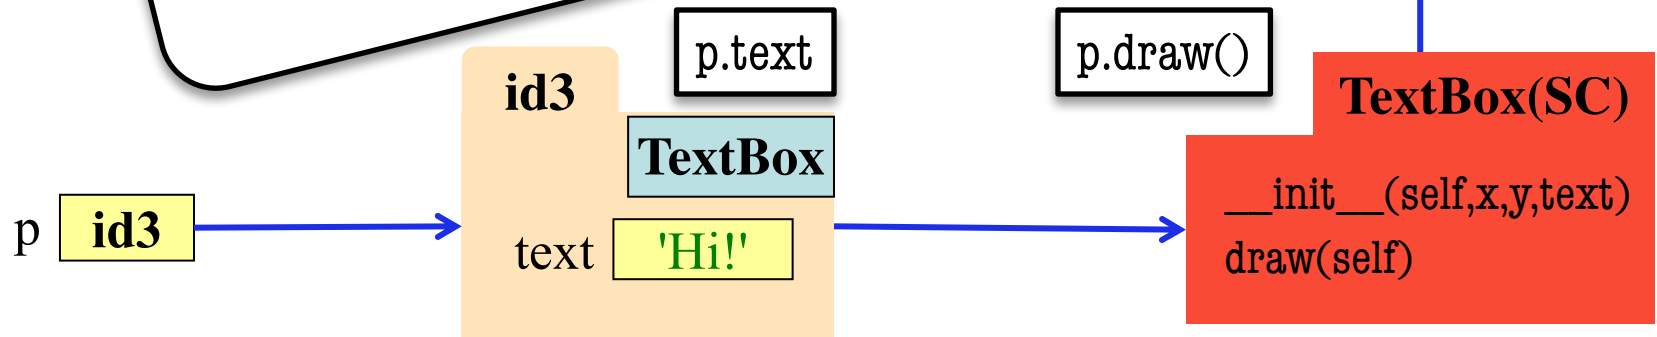

# Name Resolution Revisited

- To look up attribute/method name
  1. Look first in instance (object folder)
  2. Then look in the class (folder)

- Subclasses add

3. Look
4. Re

Often Called the **Bottom-Up Rule**.  
Subclass *inherits* methods of parent.

# A Simpler Example

```
class Employee(object):
```

```
    """Instance is salaried worker
```

```
    INSTANCE ATTRIBUTES:
```

```
        _name: full name [string]
```

```
        _start: first year hired
```

```
                [int  $\geq$  -1, -1 if unknown]
```

```
        _salary: yearly wage [float]"""
```

```
class Executive(Employee):
```

```
    """An Employee with a bonus
```

```
    INSTANCE ATTRIBUTES:
```

```
        _bonus: annual bonus [float]"""
```

**object**

```
__init__(self)
```

```
__str__(self)
```

```
__eq__(self)
```

**Employee**

```
__init__(self,n,d,s)
```

```
__str__(self)
```

```
__eq__(self)
```

**Executive**

```
__init__(self,n,d,b)
```

```
__str__(self)
```

```
__eq__(self)
```

# A Simpler Example

```
class Employee(object):
```

```
    """Instance is salaried worker
```

```
    INSTANCE ATTRIBUTES:
```

```
        _name: full name [string]
```

```
        _start: first year hired
```

```
                [int  $\geq$  -1, -1 if unknown]
```

```
        _salary: yearly wage [float]"""
```

```
class Executive(Employee):
```

```
    """An Employee with a bonus
```

```
    INSTANCE ATTRIBUTES:
```

```
        _bonus: annual bonus [float]"""
```

**object**

```
__init__(self)
```

```
__str__(self)
```

```
__eq__(self)
```

All double  
underscore  
methods are  
in class object

**Employee**

```
__init__(self,n,d,s)
```

```
__str__(self)
```

```
__eq__(self)
```

**Executive**

```
__init__(self,n,d,b)
```

```
__str__(self)
```

```
__eq__(self)
```

# Method Overriding

- Which `__str__` do we use?
  - Start at bottom class folder
  - Find first method with name
  - Use that definition
- New method definitions **override** those of parent
- Also applies to
  - Initializers
  - Operators
  - Propertiesall “methods”

**object**

```
__init__(self)
__str__(self)
__eq__(self)
```

**Employee**

```
__init__(self,n,d,s)
__str__(self)
__eq__(self)
```

**Executive**

```
__init__(self,n,d,b)
__str__(self)
__eq__(self)
```

# Accessing the “Previous” Method

- What if you want to use the original version method?
  - New method = **original**+**more**
  - Do not want to repeat code from the original version
- Use the function `super()`
  - “Converts” type to parent class
  - Now methods go to the class

- **Example:**

`super().__str__()`

**In Python 2  
self goes here**

**object**

```
__init__(self)
__str__(self)
__eq__(self)
```

**Employee**

```
__init__(self,n,d,s)
__str__(self)
__eq__(self)
```

**Executive**

```
__init__(self,n,d,b)
__str__(self)
__eq__(self)
```

# Accessing the “Previous” Method

- What if you want to use the original version method?
  - New method = **original**+**more**
  - Do not want to repeat code from the original version
- Use the function `super()`
  - “Converts” type to parent class
  - Now methods go to the class

- **Example:**

`super().__str__()`

**self is implied**

```
class Employee(object):  
    """An Employee with a salary"""  
    ...  
    def __str__(self):  
        return (self._name +  
                ', year ' + str(self._start) +  
                ', salary ' + str(self._salary))
```

```
class Executive(Employee):  
    """An Employee with a bonus."""  
    ...  
    def __str__(self):  
        return (super().__str__() +  
                ', bonus ' + str(self._bonus) )
```

# Primary Application: Initializers

```
class Employee(object):  
    ...  
    def __init__(self,n,d,s=50000.0):  
        self._name = n  
        self._start = d  
        self._salary = s
```

```
class Executive(Employee):  
    ...  
    def __init__(self,n,d,b=0.0):  
        super().__init__(n,d)  
        self._bonus = b
```

**object**

```
__init__(self)  
__str__(self)  
__eq__(self)
```

**Employee**

```
__init__(self,n,d,s)  
__str__(self)  
__eq__(self)
```

**Executive**

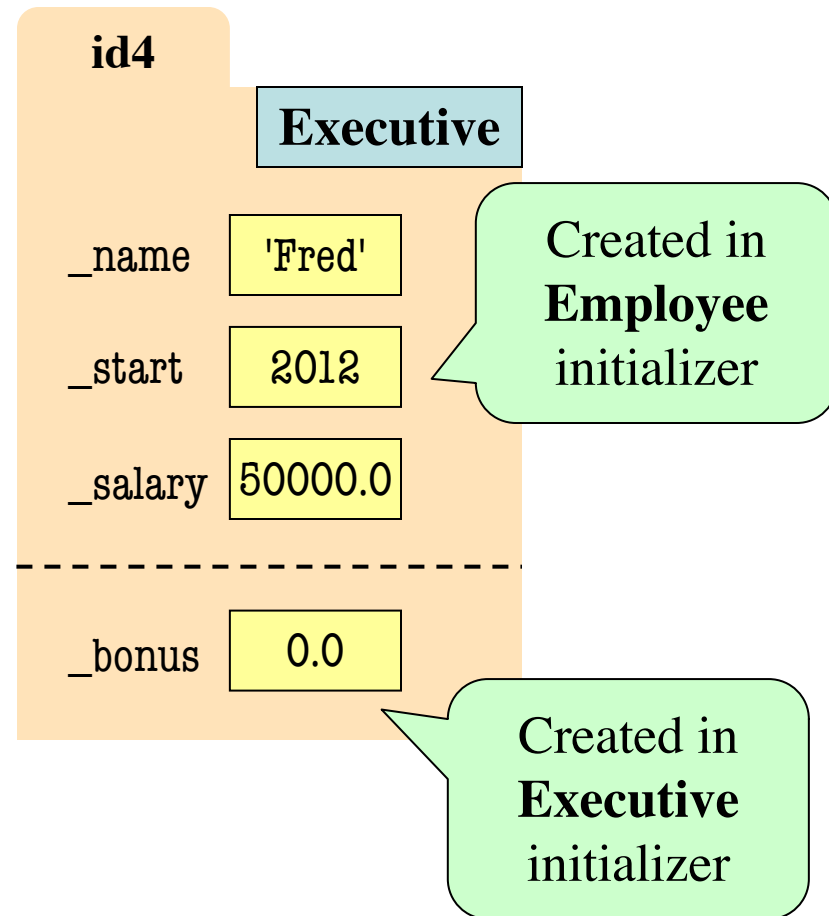

```
__init__(self,n,d,b)  
__str__(self)  
__eq__(self)
```

# Instance Attributes are (Often) Inherited

```
class Employee(object):  
    ...  
    def __init__(self,n,d,s=50000.0):  
        self._name = n  
        self._start = d  
        self._salary = s
```

```
class Executive(Employee):  
    ...  
    def __init__(self,n,d,b=0.0):  
        super().__init__(n,d)  
        self._bonus = b
```

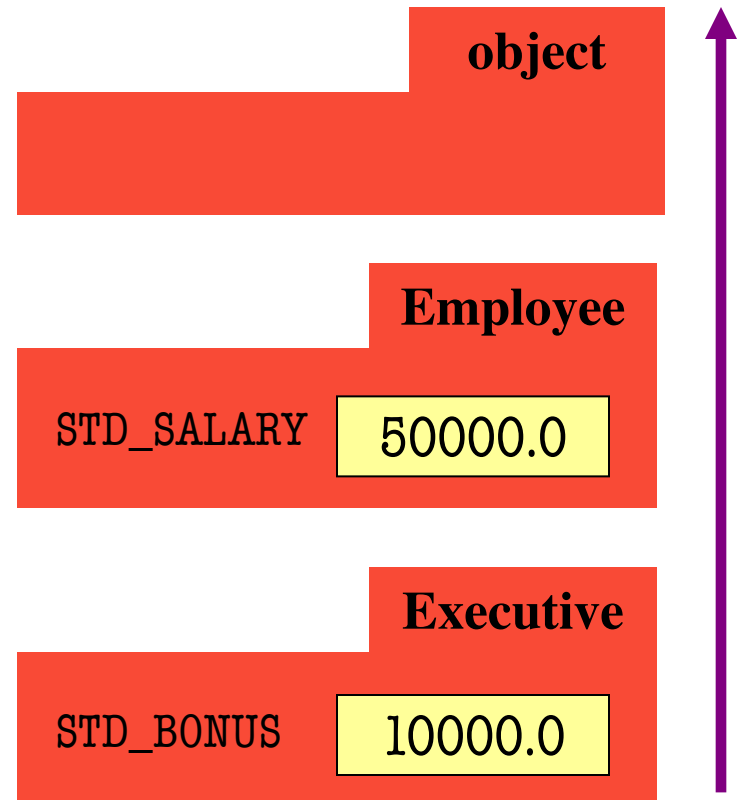

# Also Works With Class Attributes

**Class Attribute:** Assigned outside of any method definition

```
class Employee(object):  
    """Instance is salaried worker"""  
    # Class Attribute  
    STD_SALARY = 50000.0
```

```
class Executive(Employee):  
    """An Employee with a bonus."""  
    # Class Attribute  
    STD_BONUS = 10000.0
```

# Name Resolution and Inheritance

```
class A(object):
    x = 3 # Class Attribute
    y = 5 # Class Attribute

    def f(self):
        | return self.g()

    def g(self):
        | return 10
```

```
class B(A):
    y = 4 # Class Attribute
    z = 42 # Class Attribute

    def g(self):
        | return 14

    def h(self):
        | return 18
```

- Execute the following:  
    >>> a = A()  
    >>> b = B()
- What is value of a.f()?

A: 10  
B: 14  
C: 5  
D: **ERROR**  
E: I don't know

# Name Resolution and Inheritance

```
class A(object):  
    x = 3 # Class Attribute  
    y = 5 # Class Attribute  
  
    def f(self):  
        | return self.g()  
  
    def g(self):  
        | return 10
```

```
class B(A):  
    y = 4 # Class Attribute  
    z = 42 # Class Attribute  
  
    def g(self):  
        | return 14  
  
    def h(self):  
        | return 18
```

- Execute the following:  
    >>> a = A()  
    >>> b = B()  
  
• What is value of a.f()?

A: 10 **CORRECT**

B: 14

C: 5

D: **ERROR**

E: I don't know

# Name Resolution and Inheritance

```
class A(object):
    x = 3 # Class Attribute
    y = 5 # Class Attribute

    def f(self):
        | return self.g()

    def g(self):
        | return 10
```

```
class B(A):
    y = 4 # Class Attribute
    z = 42 # Class Attribute

    def g(self):
        | return 14

    def h(self):
        | return 18
```

- Execute the following:

```
>>> a = A()
```

```
>>> b = B()
```

- What is value of `b.f()`?

A: 10

B: 14

C: 5

D: **ERROR**

E: I don't know

# Name Resolution and Inheritance

```
class A(object):
    x = 3 # Class Attribute
    y = 5 # Class Attribute

    def f(self):
        | return self.g()

    def g(self):
        | return 10
```

```
class B(A):
    y = 4 # Class Attribute
    z = 42 # Class Attribute

    def g(self):
        | return 14

    def h(self):
        | return 18
```

- Execute the following:  
    >>> a = A()  
    >>> b = B()
- What is value of b.f()?

A: 10  
B: 14 **CORRECT**  
C: 5  
D: **ERROR**  
E: I don't know

# Name Resolution and Inheritance

```
class A(object):  
    x = 3 # Class Attribute  
    y = 5 # Class Attribute  
  
    def f(self):  
        | return self.g()  
  
    def g(self):  
        | return 10
```

```
class B(A):  
    y = 4 # Class Attribute
