

Lecture 17

Classes

Announcements for This Lecture

Assignments

- **A4 Thursday** at midnight
 - Hopefully you are on Task 4
 - Minor extension for reasons
- Will post **A5** on Wednesday
 - Written assignment like A2
 - Needs material from Tues
- Will post **A6** on *Friday*
 - Not due until November 14
 - Want to avoid exam crunch

Lab this Week

- More prelim exercises
 - This time for-loops
 - Plus a simple class

Exams

- Last week for regrades
 - Limit them to valid issues
- Getting closer to prelim 2

Recall: Objects as Data in Folders

- An object is like a **manila folder**
- It contains other variables
 - Variables are called **attributes**
 - Can change values of an attribute (with assignment statements)
- It has a “tab” that identifies it
 - Unique number assigned by Python
 - Fixed for lifetime of the object

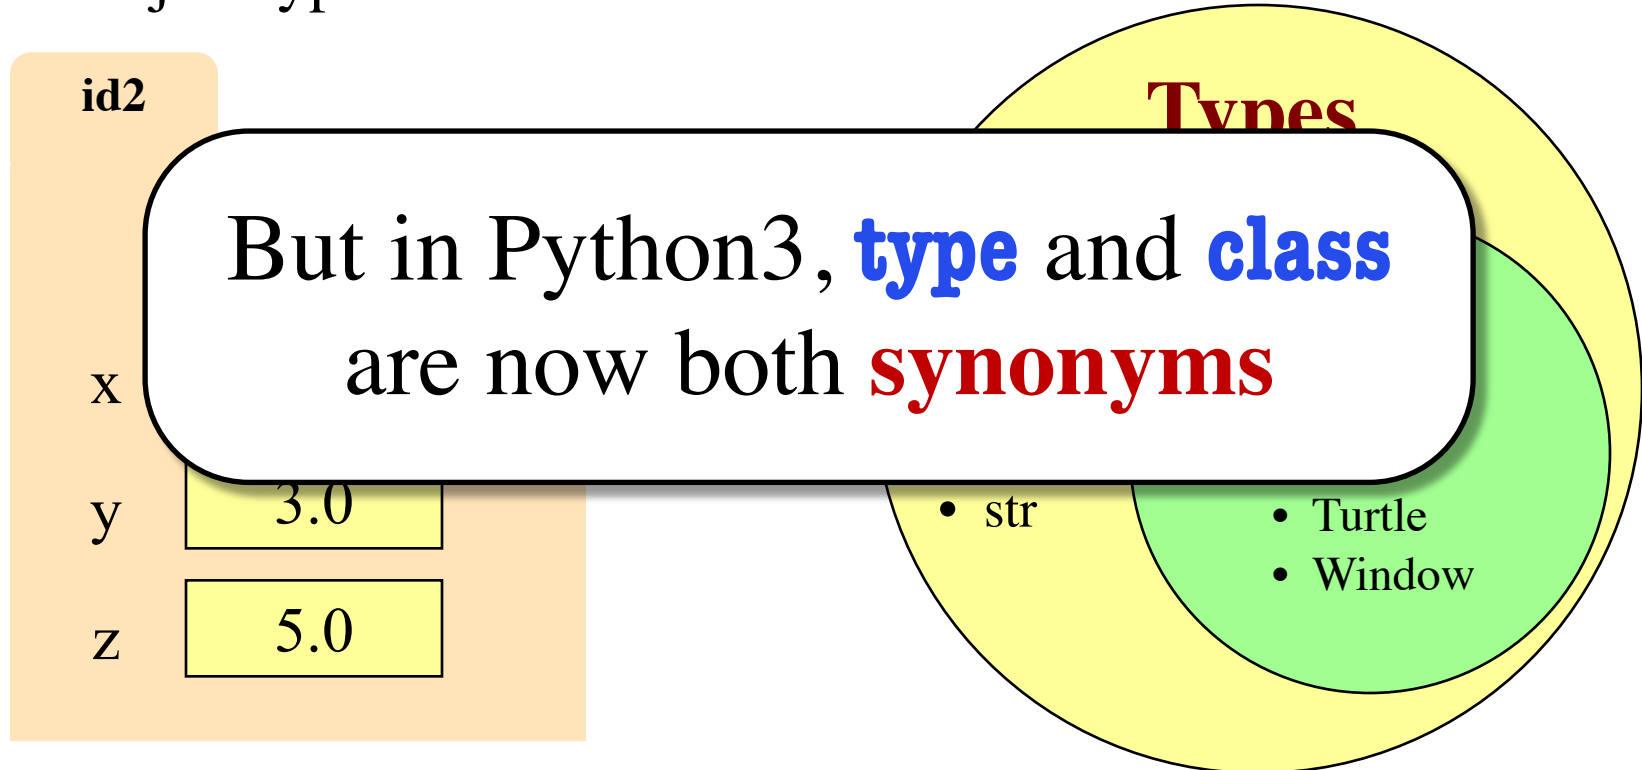

Recall: Classes are Types for Objects

- Values must have a type
 - An object is a **value**
 - Object type is a **class**
- Classes are how we add new types to Python

Recall: Classes are Types for Objects

- Values must have a type
 - An object is a **value**
 - Object type is a **class**
- Classes are how we add new types to Python

Classes Have Folders Too

Object Folders

- Separate for each *instance*

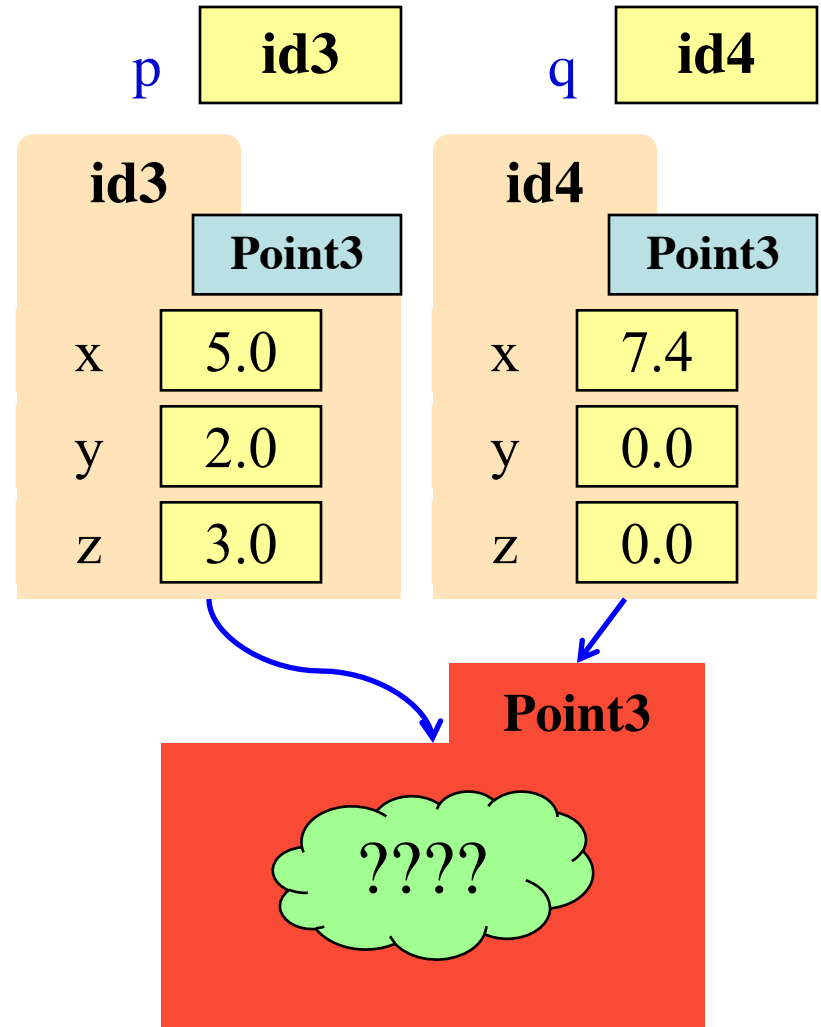

Class Folders

- Data common to all instances

Name Resolution for Objects

- $\langle object \rangle . \langle name \rangle$ means
 - Go the folder for *object*
 - Find attribute/method *name*
 - If missing, check **class folder**
 - If not in either, raise error
- What is in the class folder?
 - Data common to **all** objects
 - First must understand the *class definition*

The Class Definition

Goes inside a module, just like a function definition.

class *<class-name>*(object):

```
    """Class specification"""
```

```
    <function definitions>
```

```
    <assignment statements>
```

```
    <any other statements also allowed>
```

```
class Example(object):  
    """The simplest possible class."""  
    pass
```

Example

The Class Definition

Goes inside a module, just like a function definition.

keyword **class**
Beginning of a class definition

class *<class-name>*(object):

Do not forget the colon!

Specification
(similar to one for a function)

"""Class specification"""

more on this later

<function definitions>

to define **methods**

<assignment statements>

...but not often used

to define **attributes**

<any other statements also allowed>

```
class Example(object):  
    """The simplest possible class."""  
    pass
```

Example

Python creates after reading the class definition

Recall: Constructors

- Function to create new instances
 - Function name == class name
 - Created for you automatically
- Calling the constructor:
 - Makes a new object folder
 - Initializes attributes
 - Returns the id of the folder
- By default, takes no arguments
 - `e = Example()`

Will come back to this

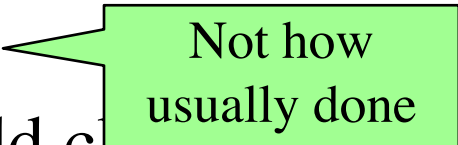

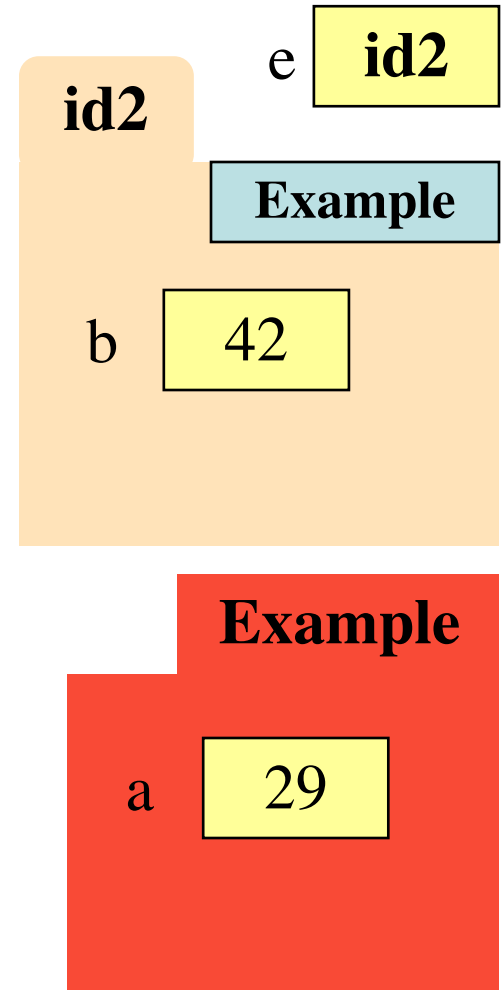

Instances and Attributes

- Assignments add object attributes
 - `<object>.<att> = <expression>`
 - **Example:** `e.b = 42`
- Assignments can add class attributes
 - `<class>.<att> = <expression>`
 - **Example:** `Example.a = 29`
- Objects can access class attributes
 - **Example:** `print e.a`
 - But assigning it creates object attribute
 - **Example:** `e.a = 10`
- **Rule:** check object first, then class

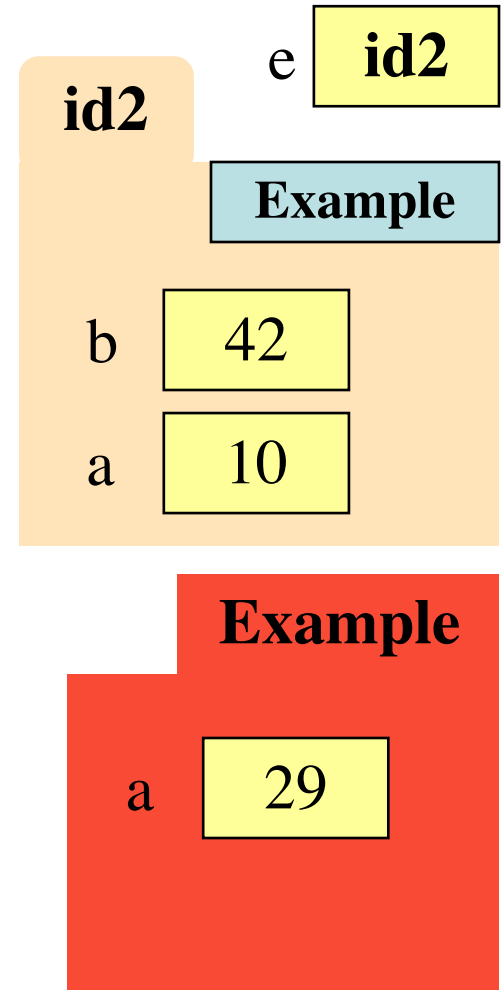

Instances and Attributes

- Assignments add object attributes
 - `<object>.<att> = <expression>`
 - **Example:** `e.b = 42` 
- Assignments can add class attributes
 - `<class>.<att> = <expression>`
 - **Example:** `Example.a = 29`
- Objects can access class attributes
 - **Example:** `print e.a`
 - But assigning it creates object attribute
 - **Example:** `e.a = 10`
- **Rule:** check object first, then class

Instances and Attributes

- Assignments add object attributes
 - `<object>.<att> = <expression>`
 - **Example:** `e.b = 42`
- Assignments can add class attributes
 - `<class>.<att> = <expression>`
 - **Example:** `Example.a = 29`
- Objects can access class attributes
 - **Example:** `print e.a`
 - But assigning it creates object attribute
 - **Example:** `e.a = 10`
- **Rule:** check object first, then class

Invariants

- Properties of an attribute that must be true
- Works like a precondition:
 - If invariant satisfied, object works properly
 - If not satisfied, object is “corrupted”
- **Examples:**
 - **Point3** class: all attributes must be floats
 - **RGB** class: all attributes must be ints in 0..255
- Purpose of the **class specification**

The Class Specification

```
class Worker(object):
```

```
    """An instance is a worker in an organization.
```

```
    Instance has basic worker info, but no salary information.
```

```
    ATTRIBUTES:
```

```
        lname: Worker's last name. [str]
```

```
        ssn: Social security no. [int in 0..999999999]
```

```
        boss: Worker's boss. [Worker, or None if no boss]
```

The Class Specification

```
class Worker(object):
```

Short
summary

```
    """An instance is a worker in an organization.
```

More
detail

```
    Instance has basic worker info, but no salary information.
```

Attribute
list

Description

```
    ATTRIBUTES:
```

Invariant

```
    lname: Worker's last name. [str]
```

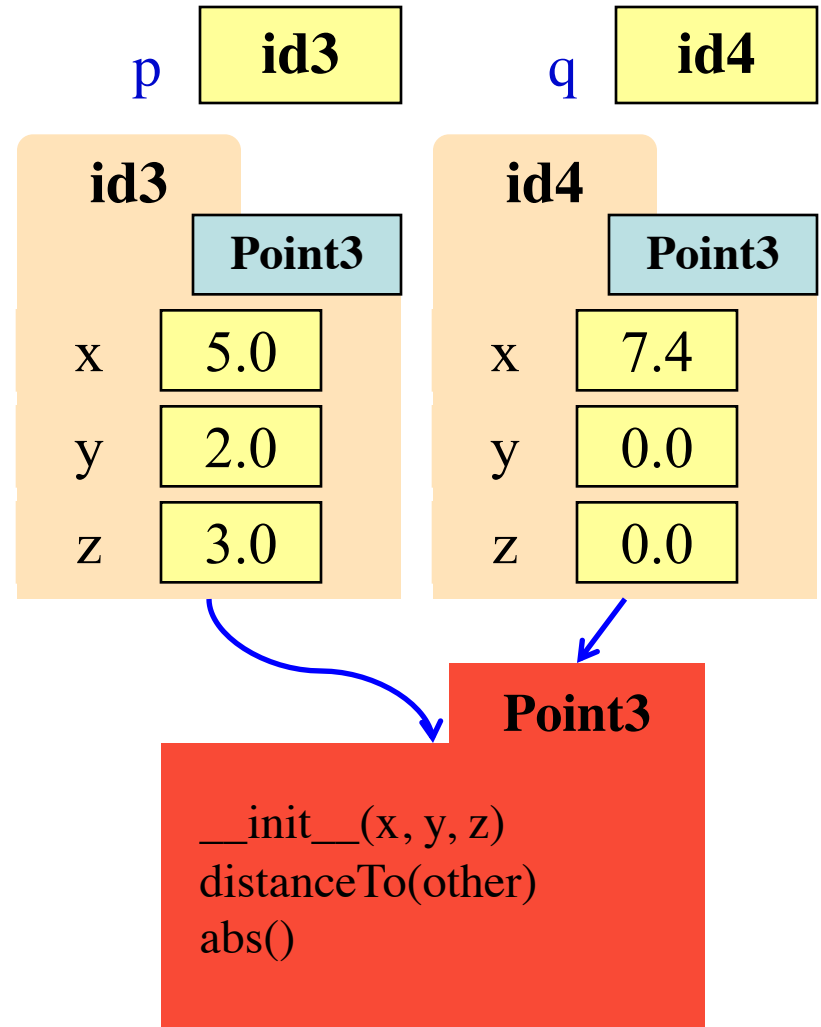

```
    ssn: Social security no. [int in 0..999999999]
```

```
    boss: Worker's boss. [Worker, or None if no boss]
```

Attribute
Name

Recall: Objects can have Methods

- **Method**: function tied to object
 - Function call:
`<function-name>(<arguments>)`
 - Method call:
`<object-variable>.<function-call>`
- **Example**: `p.distance(q)`
 - Both `p` and `q` act as arguments
 - Very much like `distanceTo(p, q)`
- For most Python objects
 - **Attributes** are in **object** folder
 - **Methods** are in **class** folder

Method Definitions

- Looks like a function def
 - But indented *inside* class
 - The first parameter is always called `self`
- In a method call:
 - Parentheses have one less argument than parameters
 - The object in front is passed to parameter `self`
- **Example:** `a.distance(b)`

self

q

```
class Point3(object):
```

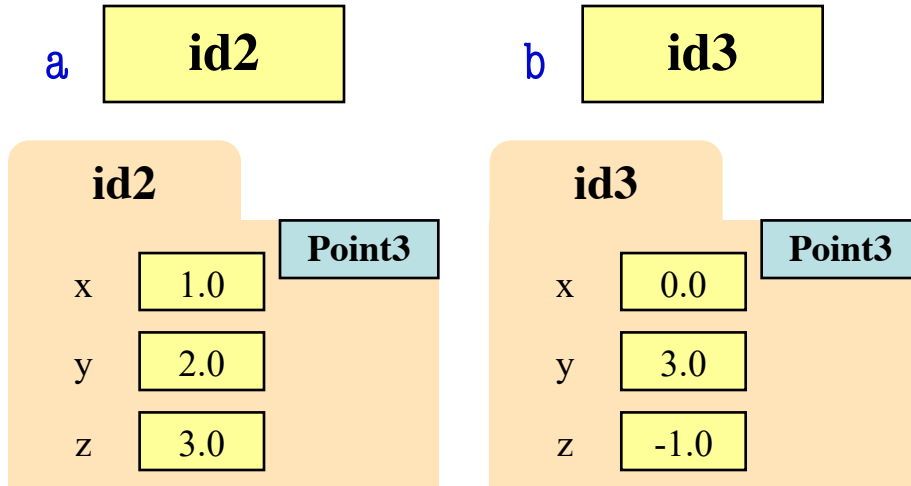

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
    def distance(self,q):
```

```
        """Returns: dist from self to q
           Precondition: q a Point3"""
        assert type(q) == Point3
        sqrdst = ((self.x-q.x)**2 +
                  (self.y-q.y)**2 +
                  (self.z-q.z)**2)
        return math.sqrt(sqrdst)
```

Methods Calls

- **Example:** `a.distance(b)`

```
class Point3(object):
```

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
def distance(self,q):
```

```
    """Returns: dist from self to q
       Precondition: q a Point3"""
```

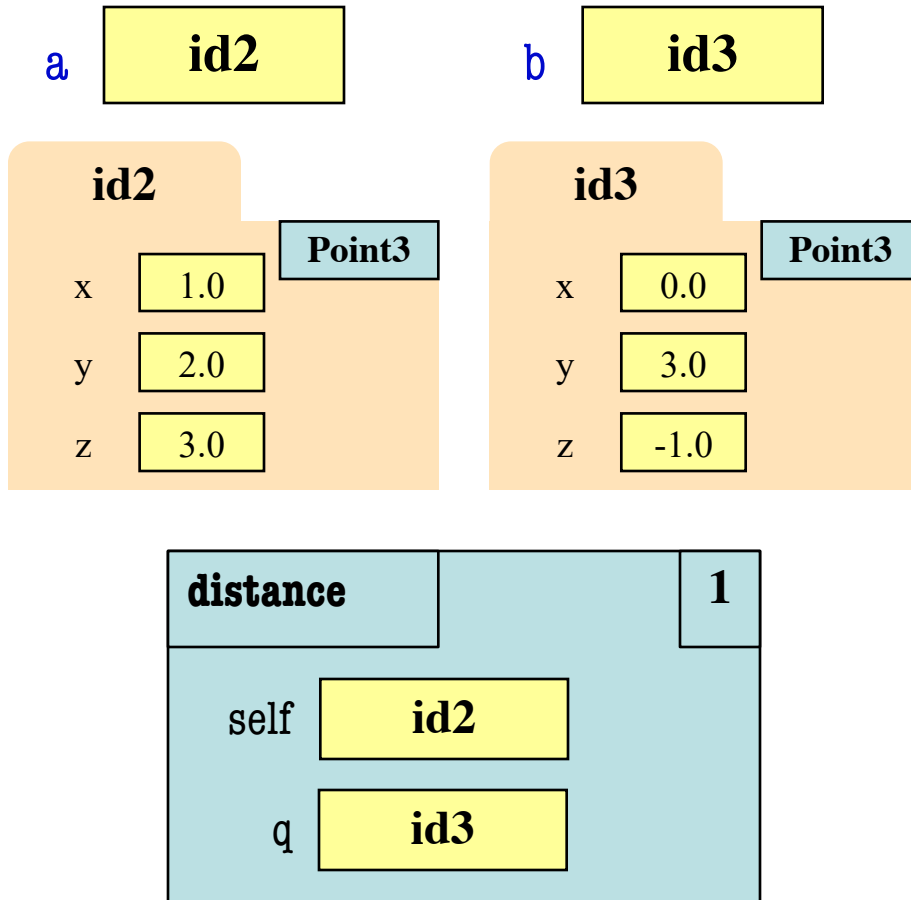

```
    assert type(q) == Point3
```

```
    sqrdst = ((self.x-q.x)**2 +
              (self.y-q.y)**2 +
              (self.z-q.z)**2)
```

```
    return math.sqrt(sqrdst)
```

Methods Calls

- **Example:** `a.distance(b)`

```
class Point3(object):
```

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
def distance(self,q):
```

```
    """Returns: dist from self to q
       Precondition: q a Point3"""
```

```
    assert type(q) == Point3
```

```
    sqrdst = ((self.x-q.x)**2 +
              (self.y-q.y)**2 +
              (self.z-q.z)**2)
```

```
    return math.sqrt(sqrdst)
```

Initializing the Attributes of an Object (Folder)

- Creating a new Worker is a multi-step process:
 - `w = Worker()` ← Instance is empty
 - `w.lname = 'White'`
 - ...
- Want to use something like
 - `w = Worker('White', 1234, None)`
 - Create a new Worker **and** assign attributes
 - lname to 'White', ssn to 1234, and boss to None
- Need a **custom constructor**

Special Method: `__init__`

```
w = Worker('White', 1234, None)
```

```
def __init__(self, n, s, b):  
    """Initializer: creates a Worker  
    Has last name n, SSN s, and boss b  
  
    Precondition: n a string, s an int in  
    range 0..999999999, and b either  
    a Worker or None.  
    self.lname = n  
    self.ssn = s  
    self.boss = b
```

Called by the constructor

Special Method: `__init__`

two underscores

```
w = Worker('White', 1234, None)
```

don't forget self

```
def __init__(self, n, s, b):
```

"""Initializer: creates a Worker

Has last name n, SSN s, and boss b

Precondition: n a string, s an int in range 0..999999999, and b either a Worker or None.

```
self.lname = n
```

```
self.ssn = s
```

```
self.boss = b
```

Called by the constructor

id8

Worker

lname 'White'

ssn 1234

boss None

Evaluating a Constructor Expression

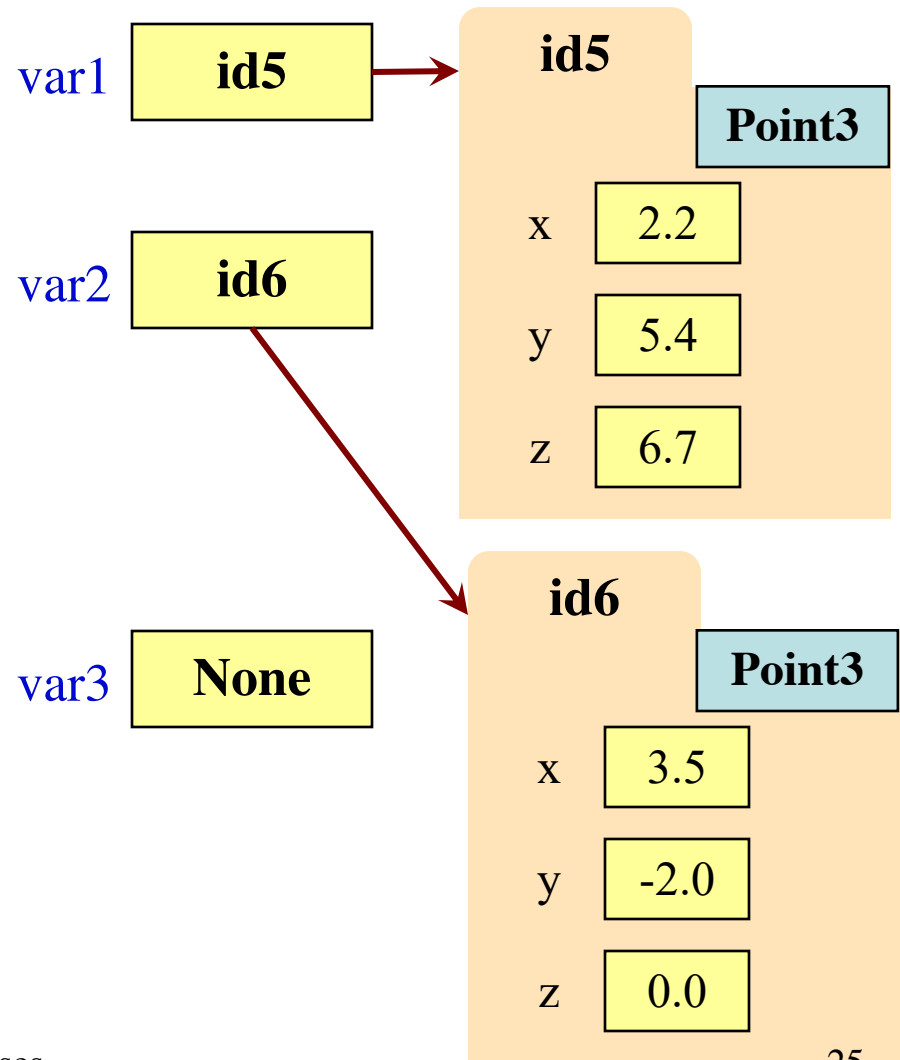

```
Worker('White', 1234, None)
```

1. Creates a new object (folder) of the class `Worker`
 - Instance is initially empty
2. Puts the folder into heap space
3. Executes the method `__init__`
 - Passes folder name to `self`
 - Passes other arguments in order
 - Executes the (assignment) commands in initializer body
4. Returns the object (folder) name

Aside: The Value None

- The boss field is a problem.
 - boss refers to a Worker object
 - Some workers have no boss
 - Or maybe not assigned yet (the buck stops there)
- **Solution:** use value None
 - **None:** Lack of (folder) name
 - Will reassign the field later!
- Be careful with None values
 - `var3.x` gives error!
 - There is no name in var3
 - Which Point to use?

Making Arguments Optional

- We can assign default values to `__init__` arguments
 - Write as assignments to parameters in definition
 - Parameters with default values are optional

- **Examples:**

- `p = Point3()` # (0,0,0)
- `p = Point3(1,2,3)` # (1,2,3)
- `p = Point3(1,2)` # (1,2,0)
- `p = Point3(y=3)` # (0,3,0)
- `p = Point3(1,z=2)` # (1,0,2)

```
class Point3(object):
```

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
    def __init__(self,x=0,y=0,z=0):
```

```
        """Initializer: makes a new Point
           Precondition: x,y,z are numbers"""
```

```
        self.x = x
```

```
        self.y = y
```

```
        self.z = z
```

```
    ...
```

Making Arguments Optional

- We can assign default values to `__init__` arguments
 - Write as assignments to parameters in definition
 - Parameters with default values are optional

- **Examples:**

- `p = Point3()` # (0,0,0)
- `p = Point3(1,2)` Assigns in order
- `p = Point3(1,z=2)` Use parameter name when out of order
- `p = Point3(y=3)` # (0,3,0)
- `p = Point3(1,z=2)` Can mix two approaches

```
class Point3(object):
```

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
    def __init__(self,x=0,y=0,z=0):
```

```
        """Initializer: makes a new Point
           Precondition: x,y,z are numbers"""
```

```
        self.x = x
```

```
        self.y = y
```

```
        self.z = z
```

Making Arguments Optional

- We can assign default values to `__init__` arguments
 - Write as assignments to parameters in definition
 - Parameters with default values are optional

- **Examples:**

- `p = Point3()` # (0,0,0)
- `p = Point3(1,2)` Assigns in order
- `p = Point3(1,z=2)` Use parameter name when out of order
- `p = Point3(y=3)` # (0,3,0)
- `p = Point3(1,z=2)` Can mix two approaches

```
class Point3(object):
```

```
    """Instances are points in 3d space
       x: x coord [float]
       y: y coord [float]
       z: z coord [float]    """
```

```
    def __init__(self,x=0,y=0,z=0):
```

```
        """Initializer: makes a new P
           Precondition:
```

Not limited to methods.
Can do with any function.
