

Module 29

Coroutines

What is Multitasking?

- In CS 1110 you create simple programs
 - You run the script in the Terminal
 - Program runs until done (or you quit)
 - Only then does Terminal “return” control
- But computers multiple programs at once
 - We can switch between without quitting
 - Some run simultaneously (playing music)
 - This is what we call **multitasking**
- Can we do something like this in Python?

But There are Two Types

Concurrency

- All programs *make progress*
 - Switch between programs
 - Switches are very fast (μs)
- Looks/feels simultaneous

Multitasking on
old hardware

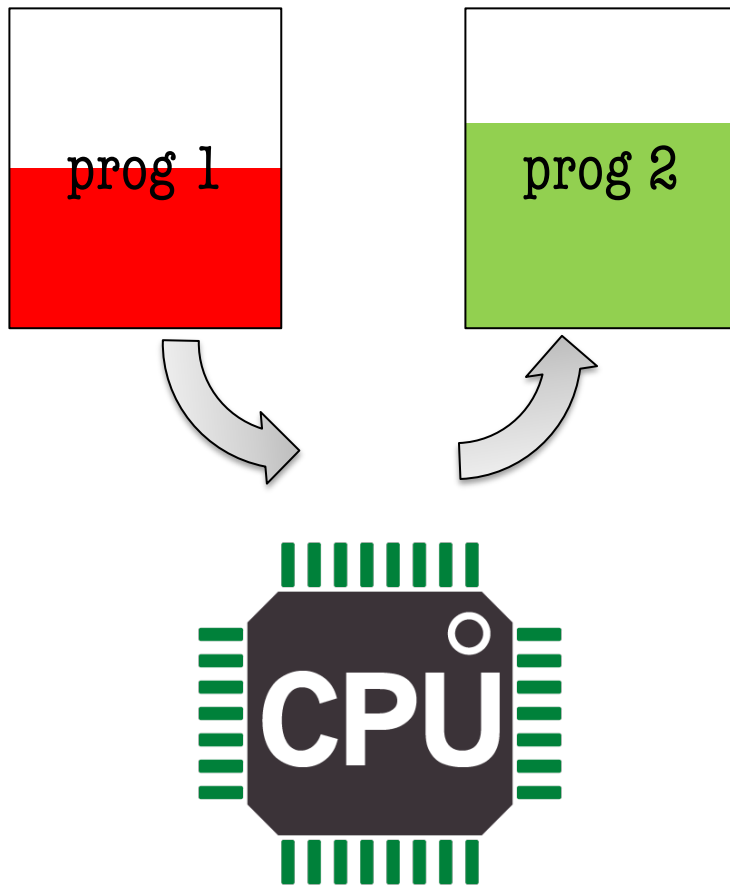

Parallelism

- Programs *run at same time*
 - Each program gets CPU/core
 - No switching between progs
- Actually is simultaneous

Multitasking on
modern hardware

An Important Distinction

Concurrency

Parallelism

Switching in Currency

Preemptive

- Can switch at any time
 - Even in middle of command!
 - Cannot prevent switching
- Very **hard to program** for
 - Must prepare for anything!
 - Debugging is a total nightmare
- Popularized by Unix systems
 - Many users on one machine
 - All need “equal” access

Cooperative

- Only switch at special points
 - Program specifies when okay
 - Returns back to this spot
- Can be easily **abused**
 - Program never specifies okay
 - That program hogs machine
- Popular in early days of GUIs
 - Okay for main app to hog
 - No expectation of other apps

Switching in Currency

Preemptive

- Can switch at any time
 - Even in middle of command!
 - Cannot prevent switching
- **Implement with threads**
- Popularized by Unix systems
 - Many users on one machine
 - All need “equal” access

Cooperative

- Only switch at special points
 - Program specifies when okay
 - Returns back to this spot
- **Implement with coroutines**
- Popular in early days of GUIs
 - Okay for main app to hog
 - No expectation of other apps

Preemptive Largely Won Out

- Modern OSs moved away from cooperative
 - Windows went preemptive with Windows 95
 - MacOS went preemptive with MacOS X
- Why? The rise of **parallelism**
 - Threads can be concurrent **and** parallel
 - Coroutines are not (easily) parallel
- But threads have **never** gotten easier
 - We have tried for decades (many PhD theses)
 - Still the source of a lot of buggy code

But Coroutines Are Coming Back

- Have figured better ways to parallelize
 - Not as good as threads in general
 - But better/easier for certain applications
- Sometimes explicit coordination is good
 - **Example:** Client-server communication
 - One waits for the other until it responds
- And again relevant to graphical applications
 - They make a lot of animation code easier
 - Used heavily by the Unity game engine

Terminology: Subroutine

- A **subroutine** is a piece of code that
 - Is a set of frequently used instructions
 - Performs a specific task, packaged as a unit
 - Often serves to aid a larger program (routine)
- This sounds just like a function!
 - Not all programming languages have functions
 - This is a generic term that applies to all
- Not a term commonly in use these days

Subroutines vs Coroutines

Subroutine

- Runs until completed
 - Invoked by parent routine
 - Runs until reach the end
 - Returns output to parent
- Just like a function call
 - Parent is “frozen”
 - Subroutine/function runs
 - Parent resumes when done

Coroutine

- Can stop and start
 - Runs for a little while
 - Returns control to parent
 - And then picks up again
- *Kind of* like a generator
 - Starts up at initial call
 - Can yield execution
 - Resumes with full state

Subroutines vs Coroutines

Subroutine

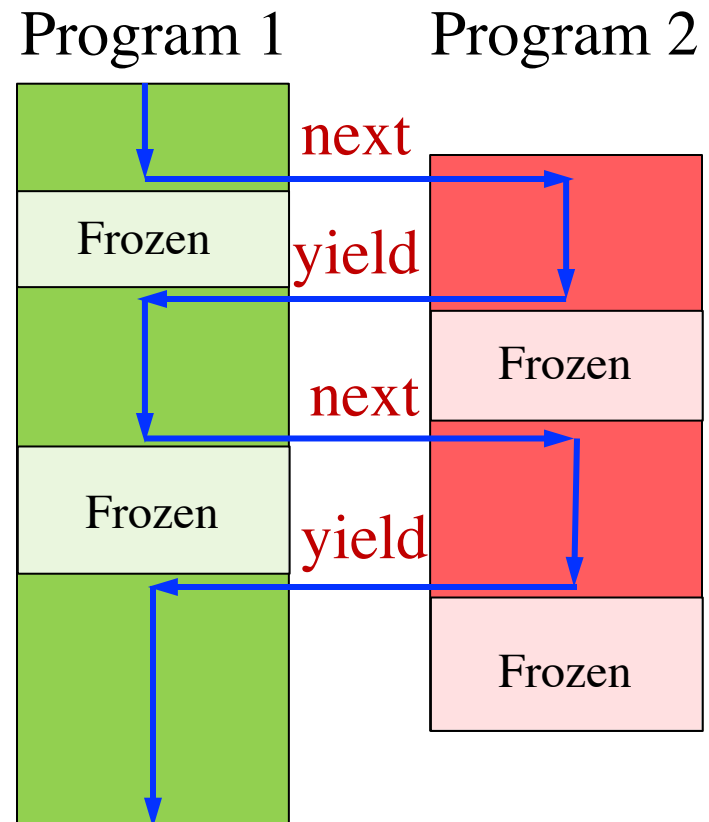

Coroutine

Subroutines vs Coroutines

Subroutine

Coroutine

Application: Counting Words

```
counts = { }           # Store the word count
word = ""              # Accumulator to build word
for x in text:
    if x.isalpha():    # Word continues
        | word = word+x
    else:              # Word ends
        | # Add it if not empty
        | if word != "":
        |     | add_word(word,counts)
        | word = ""    # Reset the accumulator
```

read0.py

What if text
is really long?

Progress Monitoring

- Want some way to measure progress
 - Graphical progress bar
 - Or even just print statements
- But do not want it inside the function
 - Want the user to be able to customize this
 - So the **calling function** monitors progress
- No way to do with simple function
 - We only know the progress when complete

Application: Counting Words

```
for pos in range(len(text)):
    if pos % interval == 0:
        yield progress
    if x.isalpha():      # Word continues
        word = word+x
    else:                # Word ends
        # Add it if not empty
        if word != "":
            add_word(word,counts)
        word = ""        # Reset the accumulator
```

Periodically
notify caller

read1.py

The Parent Caller

```
loader = wordcount(file)      # Create coroutine  
result = None
```

read1.py

```
# Keep going as long as the loader has more
```

```
while not loader is None:
```

```
    try:
```

```
        amount = next(loader)    # Load some more data
```

```
        show_progress(amount)
```

```
    except StopIteration as e:
```

```
        result = e.args[0]      # Access the return value
```

```
        loader = None          # We are done
```

Can Interleave Multiple Coroutines

```
loader1 = wordcount(file1)
```

```
loader2 = wordcount(file2)
```

```
progress1 = next(loader1)
```

```
progress2 = next(loader2)
```

```
progress1 = next(loader1)
```

```
progress2 = next(loader2)
```

```
....
```

read2.py

So Are Coroutines Just Generators?

- Generators are an **example** of a coroutine
 - Have parent child relationship
 - Use `next()` to transfer control to child
 - Child uses `yield` to transfer control back
- But coroutines are a little bit more
 - There is communication **back-and-forth**
 - `Yield` can give information back to parent
 - But `next` gives no information to child

So Are Coroutines Just Generators?

- Generators are an **example** of a coroutine
 - Have parent child relationship
 - Use next() to transfer control to child
 - Child uses yield to transfer control back
- But coroutines are a little bit more
 - The
 - Yie
 - But

Need another command

Recall: The **yield** Statement

- **Format:** `yield <expression>`
 - Used to produce a value
 - But it **does not stop** the “function”
 - Useful for making iterators
- **But:** These are not normal functions
 - Pre
 - Fur

How do other direction?

Generators Have a **send** Method

- Generators have a `send()` method
 - `a = mygenerator()`
 - `b = next(a)` # progress and get a value
 - `a.send(val)` # sends a value back
- Sends to a **yield expression**
 - **Format:** `(yield)` # parentheses are necessary
 - Typically used in an assignment
 - **Example:** `value = (yield)`

Generators Have a **send** Method

- Generators have a `send()` method
 - `a = mygenerator`
 - `b = next(a)` # `a` value
 - `a.send(val)` # sends a value back
- Sends to a **yield expression**
 - **Format:** `(yield)` # parentheses are necessary
 - Typically used in an assignment
 - **Example:** `value = (yield)`

Must always
start with `next()`

Continue to move forward with send()

Can Do Both Output and Input

- **Format:** `var = (yield expr)`
 - Coroutine evaluates `expr` and outputs it
 - Coroutine stops and lets parent resume
 - When coroutine resumes, new value in `var`
- **Example:**

```
def give_receive(n):  
    """Receives n values as input and prints them"""  
    for x in range(n):  
        value = (yield x)  
        print('Received '+repr(value))
```

Animation in Assignment 7

- **Naïve** animations are easy
 - Look at the key input right now
 - Move the objects based on the keys
 - Redraw the moved objects
- **Timed** animations are harder
 - Press a key to start the animation
 - Animation continues for X seconds
 - Animation stops automatically when done

`animate1.py`

`animate2.py`

Timed Animation Example

```
def update(self,dt):  
    """Animates the image."""  
    if self._animating:  
        if self._rotation:  
            self._animate_turn(dt)  
        else:  
            self._animate_slide(dt)  
    elif self.input.is_key_down('left'):  
        self._animating = True  
        self._rotation = True  
        self._sangle = self.image.angle  
        self._fangle = self._sangle+90  
    ...
```

Ignore input if
still animating

Otherwise start
animation for
given input

Timed Animation Example

```
def _animate_turn(self,dt):  
    """Animates a rotation of the image over SPEED seconds"""  
    # Compute degrees per second  
    steps = (self._fangle-self._sangle)/SPEED  
    amount = steps*dt  
    # Update the angle  
    self.image.angle = self.image.angle+amount  
    # If we go to far, clamp and stop animating  
    if abs(self.image.angle-self._sangle) >= 90:  
        self.image.angle = self._fangle  
        self._animating = False
```

dt tells how
far to animate

Animation Needs Many Attributes

```
def _animate_turn(self,dt):
```

```
    """ New Attribute n of the image over SPEED seconds """
```

```
    # Compute degrees per second
```

```
    steps = (self._fangle-self._sangle)/SPEED
```

```
    amount = steps*dt
```

New Attribute

```
    # Update the angle
```

```
    self.image.angle = self.image.angle+amount
```

```
    # If we go to far, clamp and stop animating
```

```
    if (self.image.angle-self._sangle) >= 90:
```

```
        self.image.angle = self._fangle
```

```
        self._animating = False
```

Animation Needs Many Attributes

```
def _animate_turn(self,dt):
```

```
    """ New Attribute n of the image over SPEED seconds """
```

```
    # Compute degrees per second
```

```
    steps = (
```

```
    amount
```

```
    # Update
```

```
    self.image
```

```
    # If we go too far, clamp and stop animating
```

```
    if (self._fangle - self._sangle) >= 90:
```

```
        self.image._angle = self._fangle
```

```
        self._animating = False
```

Is there a simpler
way to do this?

Same Animation With Coroutines

```
def update(self,dt):
    """Animates the image."""
    if not self._animator is None:      # Something to animate
        try:
            self._animator.send(dt)     # Tell it secs to animate
        except:
            self._animator = None       # Stop animating
    elif self.input.is_key_down('left'):
        self._animator = self._animate_turn('left')
        next(self._animator)            # Start up the animator
    ...
```

Same Animation With Coroutines

```
def update(self,dt):  
    """Animates the image."""  
    if not self._animator is None: # Something to animate  
        try:  
            self._animator.send(dt) # Ignore input if  
        # still animating  
        except:  
            self._animator = None # Stop animating  
    elif self.input.is_key_down('left'):  
        self._animator = self._animate_turn # Otherwise start  
        next(self._animator) # animation for  
        # given input  
    ...
```

Same Animation with Coroutines

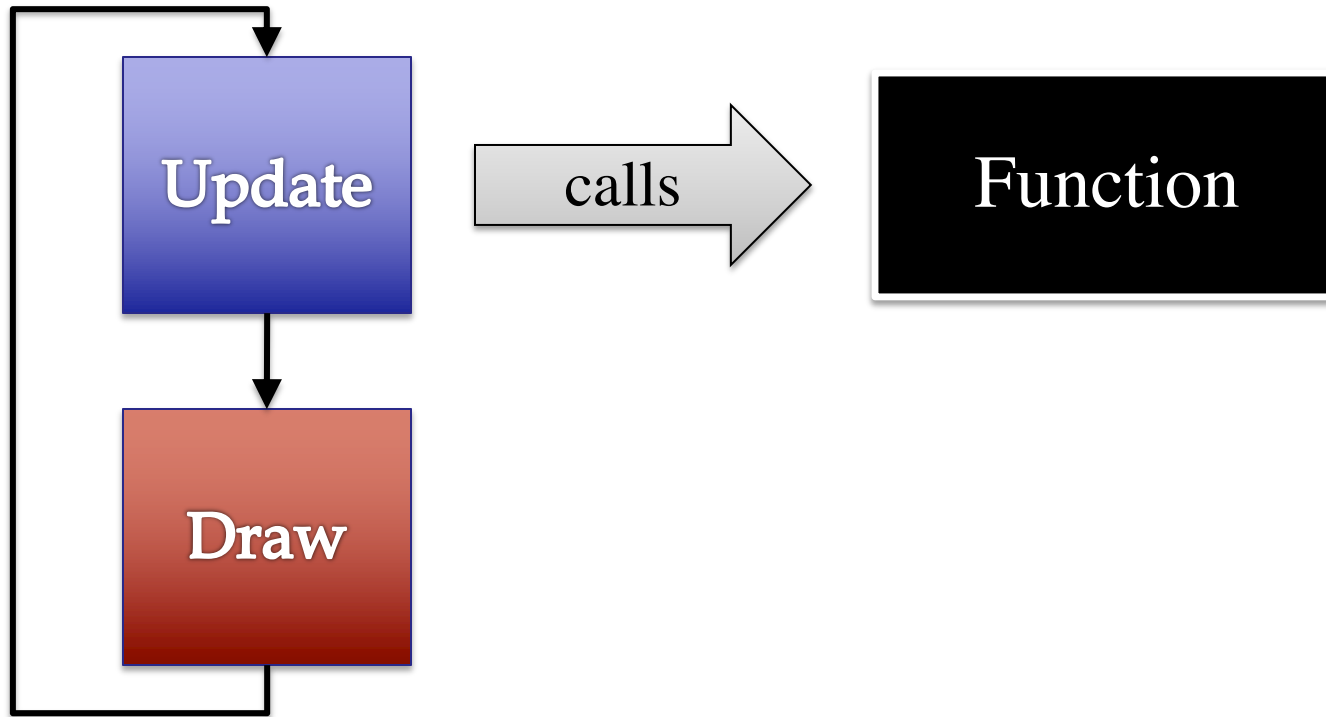

```
def _animate_turn(self,direction):
    """Animates a rotation of the image over SPEED seconds"""
    sangle = self.image.angle
    fangle = sangle+90 if direction == 'left' else sangle-90
    steps = (fangle-sangle)/ANIMATION_SPEED      # Compute degrees per second
    animating = True
    while animating:
        dt = (yield)                              # Get time to animate
        amount = steps*dt
        self.image.angle = self.image.angle+amount # Update the angle
        if abs(self.image.angle-sangle) >= 90:
            self.image.angle = fangle
            animating = False
```

Same Animation with Coroutines

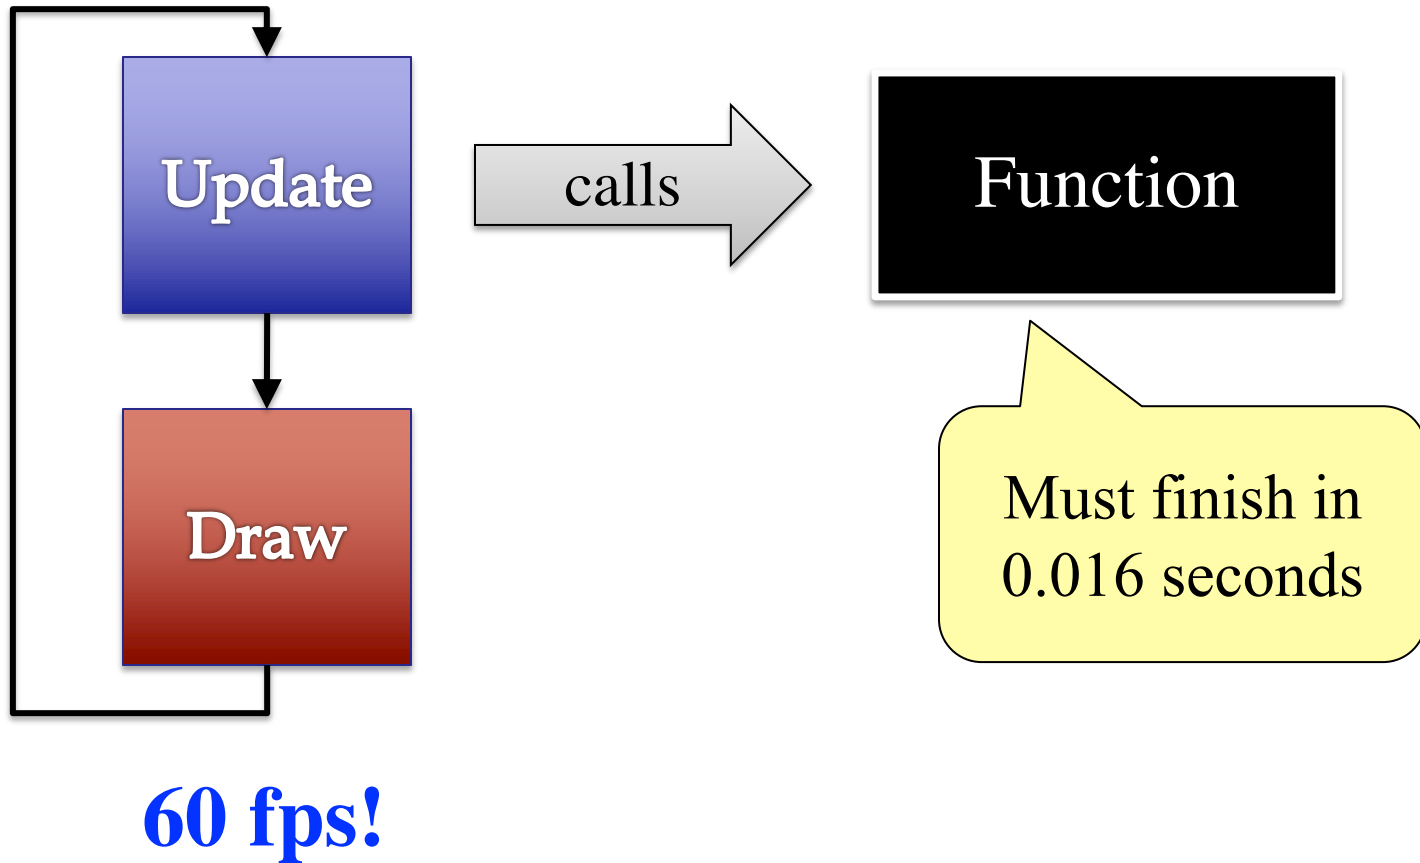

```
def _animate_turn(self,direction):  
    """Animates a rotation of the image over SPEED seconds"""  
    sangle = self.image.angle  
    fangle = sangle+90 if direction == 'left' else sangle-90  
    steps = (fangle-sangle)/ANIMATION_SPEED      # Compute degrees per second  
    animating = True  
    while animating:  
        dt = (yield)  
        amount = steps*dt  
        self.image.angle = self.image.angle+am  
        if abs(self.image.angle-sangle) >= 90:  
            self.image.angle = fangle  
            animating = False
```

Loop is explicit.
Animate until done

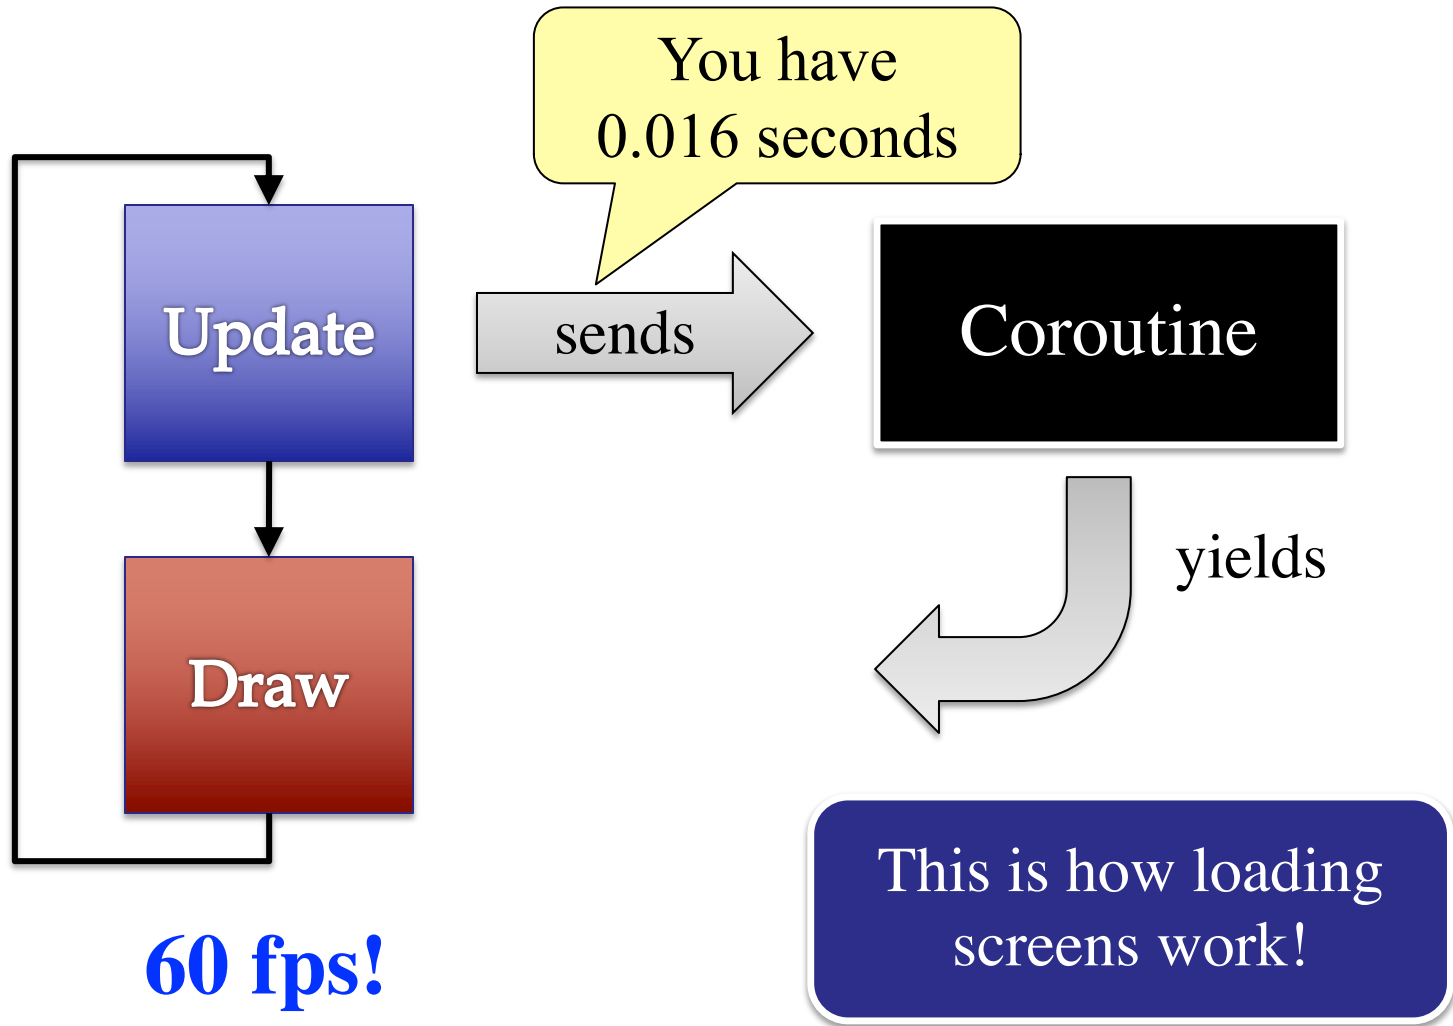

Another Application: Time Budgeting

Another Application: Time Budgeting

With a Coroutine

Application: Counting Words

```
budget = (yield)          # Get the initial budget
start = time.time()      # Start the timer
```

read3.py

```
for pos in range(len(text)):
```

```
    end = time.time()    # See if we have taken too long
```

```
    if end-start > budget:
```

```
        progress = round(100*pos/len(text))
```

```
        budget = (yield progress)    # Notify progress, get new budget
```

```
        start = time.time()          # Reset the timer for new budget
```

```
    # Build up the word, one letter at a time
```

Application: Counting Words

```
budget = (yield)
start = time.time()
```

Current time
in seconds

read3.py

```
for pos in range(len(text)):
```

```
    end = time.time()    # See if we have taken too long
```

```
    if end-start > budget:
```

```
        progress = round(100*pos/len(text))
```

```
        budget = (yield progress)    # Notify progress, get new budget
```

```
        start = time.time()          # Reset the timer for new budget
```

```
    # Build up the word, one letter at a time
```

Python Now Has **Native Coroutines**

- No longer just a generator variation
 - Supported since Python 3.5
 - Requires the `asyncio` module
- **Advantages**
 - A lot less code to write
 - Much is done for you automatically
- **Disadvantages**
 - Much less flexible
 - Cannot use it for animations in A7

Three Requirements

- The `yield` expression is replaced by `await`
 - Stops until it gets an answer
 - But it is not a `yield`; does not output anything
- Function/method must start with `async`
 - Tells Python this is native coroutine
 - Presence of `await` is not enough
- Must use `asyncio` to run the coroutines
 - Top level function is `asyncio.run(...)`
 - All helpers are `asyncio.create_task(...)`

Word Count Example Revisited

```
async def loadfiles(fname1,fname2):
```

```
    """Creates a word-count dictionary for fname1, fname2"""
```

```
    # Create the tasks for the coroutines
```

```
    result1 = { }
```

```
    loader1 = asyncio.create_task(wordcount(fname1,result1))
```

```
    result2 = { }
```

```
    loader2 = asyncio.create_task(wordcount(fname2,result2))
```

```
    # Let them take over
```

```
    await loader1
```

```
    await loader2
```

```
    result = merge(result1,result2)
```

```
    print('Read a total of '+str(len(result))+ ' words.')
```

read4.py

The send() loop is
handled for you

Word Count Example Revisited

```
async def loadfiles(fname1,fname2):
```

```
    """Creates a word-count dictionary for fname1, fname2"""
```

```
    # Create the tasks for the coroutines
```

```
    result1 = {}
```

```
    loader1 = asyncio.create_task(wordcount(fname1,result1))
```

```
    result2 = {}
```

```
    loader2 = asyncio.create_task(wordcount(fname2,result2))
```

```
    # Let them take over
```

```
    await loader1
```

```
    await loader2
```

```
    result = merge(result1,result2)
```

```
    print('Read a total of '+str(len(result))+ ' words.')
```

read4.py

But cannot get
progress so far!

Why Native Coroutines?

- The generator version is better!
 - We have much more control
 - The yield expression goes back-and-forth
- But native coroutines support **parallelism**
 - Each coroutine can get its own core/thread
 - The `await` command is how we synchronize
- It is possible to *emulate* a yield
 - Requires very advanced Python (`pipe.py`)
 - Beyond the scope of this course
