# Lecture 21: More on Classes (Chapter 17)

CS 1110

Introduction to Computing Using Python

[E. Andersen, A. Bracy, D. Fan, D. Gries, L. Lee,  
S. Marschner, C. Van Loan, W. White]

# We know how to make:

---

- Class definitions
- Class specifications
- The `__init__` function
- Attributes (using `self`)
- Class attributes
- Class methods

# Method Definitions

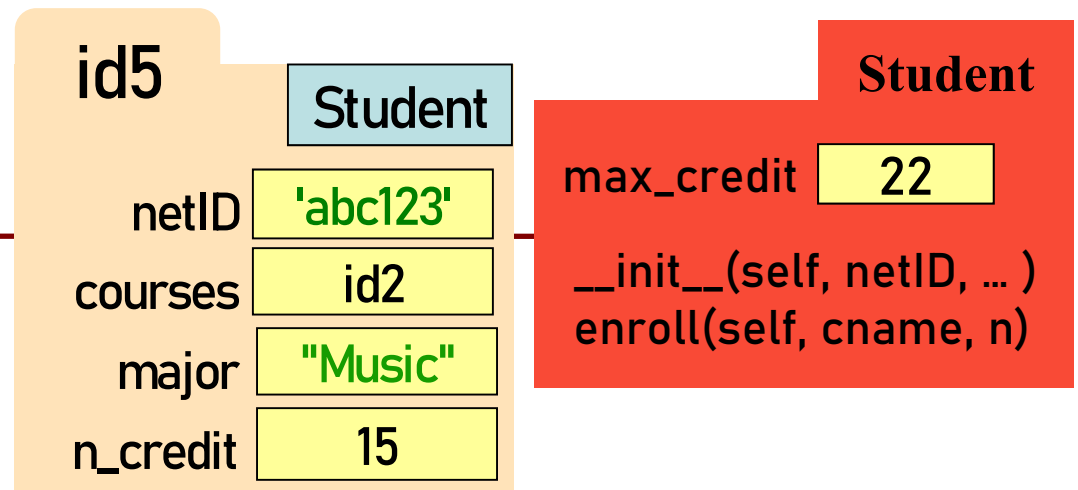

Looks like a function def

- But indented *inside* class
- 1<sup>st</sup> parameter always **self**

## Example:

`s1.enroll("AEM 2400", 4)`

- Go to class folder for **s1** (*i.e.*, **Student**) that's where **enroll** is defined
- Now **enroll** is called with **s1** as its first argument
- Now **enroll** knows which instance of **Student** it is working with

```
def __init__(self, netID, courses=[ ], major=None):  
    self.netID = netID  
    self.courses = courses  
    self.major = major  
    # < rest of init fn goes here >  
  
def enroll( self, cname, n):  
    if self.n_credit + n > Student.max_credit:  
        print("Sorry your schedule is full!")  
    else:  
        self.courses.append([cname, n])  
        self.n_credit = self.n_credit + n  
        print("Welcome to "+ cname)
```

# init is just one of many Special Methods

---

Start/end with 2 underscores

- This is standard in Python
- Used in all special methods
- Also for special attributes

`__init__` for initializer

`__str__` for `str()`

`__eq__` for `==`

`__lt__` for `<`, ...

*Optional:* for a complete list, see <https://docs.python.org/3/reference/datamodel.html#basic-customization>

```
class Point2():
```

```
    """Instances are points in 2D space"""
```

```
    ...
```

```
    def __init__(self,x=0,y=0):
```

```
        """Initializer: makes new Point2"""
```

```
        ...
```

```
    def __str__(self):
```

```
        """Returns: string with contents"""
```

```
        return '(' + str(self.x) + ', ' + str(self.y) + ')'
```

```
    def __eq__(self, other):
```

```
        """Returns: True if both coordinates equal"""
```

```
        return self.x == other.x and self.y == other.y
```

# Designing Types

---

- **Type**: set of values and the operations on them
  - **int**: (**set**: integers; **ops**: +, −, \*, /, ...)
  - **Point2** (**set**: x,y coordinates; **ops**: distanceTo, ...)
  - **Card** (**set**: suit \* rank combinations; **ops**: ==, !=, <)
  - Others to think about: **Person**, **Student**, **Image**, **Date**, *etc.*
- To define a class, think of a *type* you want to make

# Making a Class into a Type

---

1. What values do you want in the set?
  - What are the attributes? What values can they have?
  - Are these attributes shared between instances (class attributes) or different for each instance (instance attributes)?
  - What are the *class invariants*: things you promise to keep true **after every method call** (see *n\_credit invariant*)
2. What operations do you want?
  - This often influences the previous question
  - What are the *method specifications*: states what the method does & what it expects (preconditions)
  - Are there any special methods that you will need to provide?

**Write your code to make it so!**

Start next video:  
**design and implement a  
class for a game**

# Let's make a word guessing game

---

- There is a secret word.
- The user has 10 chances to guess letters until the word has been spelled out.
- Would be great to have a class **SecretWord** that would keep track of both the word we're guessing and what the user sees / has guessed so far.

**Play the game.**

# How does the game go?

---

word\_list = [ ... candidate  
                  words for user  
                  to guess ... ]

N\_GUESSES = 10

*Set the secret word*

User guesses

until no more guesses

or *secret is solved*

*Reveal the word*

# What should the SecretWord offer me?

---

Like a string, but **two** of them:

1. the secret word
2. what the user sees

I should be able to:

- Set the secret word
- Print out the word as guessed “so far”
- Determine whether the game is over
- Reveal the secret word

# Example: SecretWord

---

1. What values do you want in the set?
  - What are the attributes? What values can they have?
  - Are these attributes shared between instances (class attributes) or different for each attribute (instance attributes)?
  - What are the *class invariants*: things you promise to keep true **after every method call**
2. What operations do you want?
  - This often influences the previous question
  - What are the *method specifications*: states what the method does & what it expects (preconditions)
  - Are there any special methods that you will need to provide?

# Planning out Class: the Attributes

---

```
class SecretWord():
```

```
    """A word to be guessed by a user in a word guessing game.
```

```
    Instance Attributes:
```

```
        secret_word: word being guessed [str of lower case letters]
```

```
        display_word: word as the user sees it: the letters of secret_word show  
            correctly guessed letters [str of lower case letters and '_']
```

```
        secret_word and display_word agree on all letters and have same length
```

```
    """
```

What are the attributes? What values can they have?

Are these attributes shared between instances (class attributes) or different for each attribute (instance attributes)?

What are the *class invariants*: things you promise to keep true after every method call

# Planning out Class: the Methods

---

```
def __init__(self, word):  
    """Initializer: creates both secret_word and display_word  
    from word [a str of lower case letters]"""
```

```
def __str__(self):  
    """Returns: both words"""
```

```
def __len__(self):  
    """Returns: the length of the secret word"""
```

Are there any special methods that you will need to provide?

What are their preconditions?

*You don't have to do this. But you should consider it.*

*Careful. Make sure overloading is the right thing to do.*

# Planning out Class: the Methods

---

```
def print_word_so_far(self):
    """Prints the display_word """
def reveal(self):
    """Prints the word being guessed"""
def apply_guess(self, letter):
    """Updates the display_word to reveal all instances of letter as they
    appear in the secret_word. ('_' is replaced with letter)
    letter: the user's guess [1-character string in A.Z or a..z] """
def is_solved(self):
    """Returns True if the entire word has been guessed"""
```

What are the *method specifications*: states what the method does & what it expects (preconditions)

# How is SecretWord to be used?

---

```
import random, wordGuess
word_list = [ ... candidate
              words for user
              to guess ... ]
```

```
N_GUESSES = 10
```

*Set the secret word*

User guesses

until no more guesses

or *secret is solved*

*Reveal the word*

# How is SecretWord to be used?

---

```
import random, wordGuess
word_list = [ ... candidate
              words for user
              to guess ... ]
```

```
N_GUESSES = 10
```

*Set the secret word*

```
guess_the_word(
    secret word,
    N_GUESSES)
```

*Reveal the word*

```
if secret is solved or out of guesses
    print appropriate message and stop game
otherwise
    print the word-in-progress
    user guesses a letter
    apply guess to the secret word
    potentially guess again (is secret solved?
                             #guesses left?)
```

# How is SecretWord to be used?

---

```
import random, wordGuess
word_list = [ ... candidate
               words for user
               to guess ... ]
```

```
N_GUESSES = 10
```

*Set the secret word*

```
guess_the_word(
    secret word,
    N_GUESSES)
```

*Reveal secret word*

```
def guess_the_word(secret, n_guesses_left):
    if secret is solved:
        print("YOU WIN!!!")
    elif n_more_guesses==0:
        print("Sorry you're out of guesses")
    else:
        print the word-in-progress
        user_guess= input("Guess a letter: ")
        apply guess to the secret word
        guess_the_word(secret, n_guesses_left-1)
```

# Implementing a Class

---

- All that remains is to fill in the methods. (All?!)
- When *implementing* methods:
  1. Assume preconditions are true (*checking is friendly*)
  2. Assume class invariant is true to start
  3. Ensure method specification is fulfilled
  4. Ensure class invariant is true when done
- Later, when *using* the class:
  - When calling methods, ensure preconditions are true
  - If attributes are altered, ensure class invariant is true

# Implementing an Initializer

```
def __init__(self, word):  
    """Initializer: creates both secret_word and display_word  
    from word [a str of lower case letters] """ # JOB OF THIS METHOD
```

Instance variables: # WHAT BETTER BE TRUE WHEN WE'RE DONE  
secret\_word: [str of lower case letters]  
display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']  
secret\_word and display\_word agree on all letters and have same length

# Implementing an Initializer (Q)

```
def __init__(self, word):  
    """Initializer: creates both secret_word and display_word  
    from word [a str of lower case letters] """ # JOB OF THIS METHOD
```

A

```
SecretWord.secret_word = word  
SecretWord.display_word = '_'*len(word)
```

B

```
secret_word = word  
display_word = '_'*len(word)
```

C

```
self.secret_word = word  
self.display_word = '_'*len(word)
```

Instance variables: # WHAT BETTER BE TRUE WHEN WE'RE DONE

secret\_word: [str of lower case letters]

display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']

secret\_word and display\_word agree on all letters and have same length

# Implementing an Initializer (A)

```
def __init__(self, word):  
    """Initializer: creates both secret_word and display_word  
    from word [a str of lower case letters] """ # JOB OF THIS METHOD
```

A

```
    SecretWord.secret_word = word  
    SecretWord.display_word = '_'*len(word)
```

B

```
    secret_word = word  
    display_word = '_'*len(word)
```

C

```
    self.secret_word = word  
    self.display_word = '_'*len(word) # CORRECT!
```

Instance variables: # WHAT BETTER BE TRUE WHEN WE'RE DONE

secret\_word: [str of lower case letters]

display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']

secret\_word and display\_word agree on all letters and have same length

# Implementing apply\_guess()

---

secret\_word: [str of lower case letters] # WHAT YOU CAN COUNT ON  
display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']  
secret\_word and display\_word agree on all letters and have same length

```
def apply_guess(self, letter):  
    """Updates the display_word to reveal all instances of letter as they  
    appear in the secret_word. ('_' is replaced with letter) # JOB OF METHOD  
    letter: the user's guess [1-character string in A.Z or a..z]""" # ASSUME TRUE
```

secret\_word: [str of lower case letters] # WHAT STILL BETTER BE TRUE  
display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']  
secret\_word and display\_word agree on all letters and have same length

# Implementing apply\_guess()

secret\_word: [str of lower case letters] # WHAT YOU CAN COUNT ON  
display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']  
secret\_word and display\_word agree on all letters and have same length

```
def apply_guess(self, letter):
    """Updates the display_word to reveal all instances of letter as they
    appear in the secret_word. ('_' is replaced with letter) # JOB OF METHOD

    lower_letter = letter.lower()
    for i in range(len(self.secret_word)):
        if self.secret_word[i] == lower_letter:
            self.display_word = self.display_word[:i] + lower_letter + self.display_word[i+1:]
```

secret\_word: [str of lower case letters] # WHAT STILL BETTER BE TRUE  
display\_word: the letters of secret\_word show correctly guessed letters  
[str of lower case letters and '\_']  
secret\_word and display\_word agree on all letters and have same length

# How is SecretWord to be used?

---

```
import random, wordGuess
word_list = [ ... candidate
              words for user
              to guess ... ]
```

```
N_GUESSES = 10
```

*Set the secret word*

```
guess_the_word(
    secret word,
    N_GUESSES)
```

*Reveal secret word*

```
def guess_the_word(secret, n_guesses_left):
    if secret is solved:
        print("YOU WIN!!!")
    elif n_more_guesses==0:
        print("Sorry you're out of guesses")
    else:
        print the word-in-progress
        user_guess= input("Guess a letter: ")
        apply guess to the secret word
        guess_the_word(secret, n_guesses_left-1)
```

Start next video:  
**operator overloading**

# Planning out a Class: Fraction

---

- What *attributes*?
- What *invariants*?
- What *methods*?
- What *initializer* and other *special methods*?

```
class Fraction():
    """Instance is a fraction n/d
    Attributes:
        numerator: top    [int]
        denominator: bottom [int > 0]
    """

    def __init__(self,n=0,d=1):
        """Init: makes a Fraction"""
        assert type(n)==int
        assert type(d)==int and d>0
        self.numerator = n
        self.denominator = d
```

# Problem: Doing Math is Unwieldy

---

## What We Want

---

$$\left(\frac{1}{2} + \frac{1}{3} + \frac{1}{4}\right) * \frac{5}{4}$$

Why not use the standard Python math operations?

## What We Get

---

```
>>> p = Fraction(1,2)
>>> q = Fraction(1,3)
>>> r = Fraction(1,4)
>>> s = Fraction(5,4)
>>> (p.add(q.add(r))).mult(s)
```

Pain!

# Operator Overloading: Addition

```
class Fraction():
    """Instance attributes:
       numerator: top    [int]
       denominator: bottom [int > 0]"""
    def __add__(self,q):
        """Returns: Sum of self, q
           Makes a new Fraction
           Precondition: q a Fraction"""
        assert type(q) == Fraction
        bot = self.denominator*q.denominator
        top = (self.numerator*q.denominator+
              self.denominator*q.numerator)
        return Fraction(top,bot)
```

```
>>> p = Fraction(1,2)
>>> q = Fraction(3,4)
>>> r = p+q
```

Python  
converts to

```
>>> r = p.__add__(q)
```

Operator overloading uses  
method in object on left.

# Operator Overloading: Multiplication

```
class Fraction():
    """Instance attributes:
       numerator: top    [int]
       denominator: bottom [int > 0]"""

    def __mul__(self,q):
        """Returns: Product of self, q
           Makes a new Fraction; does not
           modify contents of self or q
           Precondition: q a Fraction"""
        assert type(q) == Fraction
        top = self.numerator*q.numerator
        bot = self.denominator*q.denominator
        return Fraction(top,bot)
```

```
>>> p = Fraction(1,2)
>>> q = Fraction(3,4)
>>> r = p*q
```

Python  
converts to

```
>>> r = p.__mul__(q)
```

Operator overloading uses  
method in object on left.

# Operator Overloading: Equality

---

- By default, `==` compares *folder IDs*, e.g., the following expression evaluates to **False**:

`Fraction(2,5)==Fraction(2,5)`

- Can implement `__eq__` to check for equivalence of two **Fractions** instead

```
class Fraction():
    """Instance attributes:
       numerator: top    [int]
       denominator: bottom [int > 0]"""

    def __eq__(self,q):
        """Returns: True if self, q equal,
           False if not, or q not a Fraction"""
        if type(q) != Fraction:
            return False
        left = self.numerator*q.denominator
        right = self.denominator*q.numerator
        return left == right
```

*Optional:*

for a complete list, see <https://docs.python.org/3/reference/datamodel.html#basic-customization>
