Lecture 21

While Loops

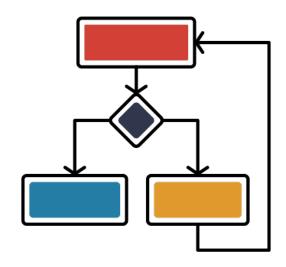

Announcements for Today

Assignments

- A4 still being graded
 - Today is last day for survey!
- A5 is due this SUNDAY
 - Shorter written assignment
 - Will grade it next week
- A6 due Mon, November 13
 - Designed to take two weeks
 - Should be on Task 2 now
 - Need material from today!

Video Lessons

- Lesson 26 for today
- Videos 23.1-23.7 for Tues
- Lessons 24, 25 for next time

Recall: The For-Loop

```
# Create local var x
x = seqn[0]
print(x)
x = seqn[1]
print(x)
            Not valid
             Python
x = seqn[len(seqn)-1]
print(x)
```

```
# Write as a for-loop
for x in seqn:
    print(x)
```

Key Concepts

- iterable: seqn
- loop variable: x
- body: print(x)

Important Concept in CS: Doing Things Repeatedly

- 1. Process each item in a sequence
 - Compute aggregate statistics for such as the mean, median, stand

for x in sequence:
process x

- Send everyone in a Facebook group an appointment time
- 2. Perform *n* trials or get *n* samples.
 - A4: draw a triangle six times to n
 - Run a protein-folding simulation

3. Do something an unknown number of times

 CUAUV team, vehicle keeps moving until reached its goal for x in range(n):
do next thing

Beyond Sequences: The while-loop

while < *condition*>: loop statement 1 condition loop statement n body true condition body false

Vs For-Loop

- Broader notion of loop
 - You define "more to do"
 - Not limited sequences
- Must manage loop var
 - You create it before loop
 - You update it inside loop
 - For-loop automated it
- Trickier to get right

while Versus for

For-Loop

While-Loop

def sum_squares(n):

"""Rets: sum of squares

Prec: n is int > 0"""

total = 0

for x in range(n):

total = total + x*x

Must remember to increment

def sum_squares(n):

"""Rets: sum of squares

Prec: n is int > 0"""

total = 0

x = 0

while x < n:

total = total + x*x

x = x+1

The Problem with While-Loops

- Infinite loops are possible
 - Forget to update a loop variable
 - Incorrectly write the boolean expression
- Will hang your program
 - Must type control-C to abort/quit
- But detecting problems is not easy
 - Sometimes your code is just slow
 - Scientific computations can take hours
- Solution: Traces

Tracing While-Loops

```
print('Before while')
                                   Output:
total = 0
                 Important
                                      Before while
\mathbf{x} = 0
                                      Start loop 0
while x < n:
                                      End loop
   print('Start loop '+str(x))
                                      Start loop 1
   total = total + x*x
                                      End loop
   x = x + 1
                                      Start loop 2
   print('End loop ')
                                      End loop
print('After while')
                                      After while
                Important
```

How to Design While-Loops

- Many of the same rules from for-loops
 - Often have an accumulator variable
 - Loop body adds to this accumulator
- Differences are loop variable and iterable
 - Typically do not have iterable
- Breaks up into three design patterns
 - 1. Replacement to range()
 - 2. Explicit goal condition
 - 3. Boolean tracking variable

While Loops and Lists

For-Loop

While-Loop

def increment_for(seq):

"""Increments each

element of seq list

Prec: seq contains ints"""

for k in range(len(seq)):

seq[k] = seq[k]+1

Must still remember to increment

def increment_while(seq):

"""Increments each

element of seq list

Prec: seq contains ints"""

$$k = 0$$

while k < len(seq):

$$seq[k] = seq[k]+1$$

$$k = k + 1$$

Using the Goal as a Condition

def prompt(prompt,valid):

"""Returns: the choice from a given prompt.

This function asks the user a question, and waits for a response. It checks if the response is valid against a list of acceptable answers.

If it is not valid, it asks the question again. Otherwise, it returns

the player's answer.

Precondition: prompt is a string

Precondition: valid is a tuple of strings"""

pass # Stub to be implemented

Tells you the stop condition

Using the Goal as a Condition

```
def prompt(prompt, valid):
   """Returns: the choice from a given prompt.
   Preconditions: prompt is a string, valid is a tuple of strings"""
   response = input(prompt)
   # Continue to ask while the response is not valid.
   while not (response in valid):
      print('Invalid response. Answer must be one of ')+str(valid)
      response = input(prompt)
   return response
```

Using a Boolean Variable

def roll_past(goal):

"""Returns: The score from rolling a die until passing goal.

This function starts with a score of 0, and rolls a die, adding the result to the score. Once the score passes goal, it stops and returns the result as the final score.

If the function ever rolls a 1, it stops and the score is 0.

Preconditions: goal is an int > 0"""
pass # Stub to be implemented

Condition is too complicated

Introduce a boolean variable.

Use it to track condition.

Using a Boolean Variable

```
def roll_past(goal):
   """Returns: The score from rolling a die until passing goal."""
   loop = True # Keep looping until this is false
   score = 0
   while loop:
      roll = random.randint(1,6)
      if roll == 1:
                                                Track the
         score = 0; loop = False
                                                condition
      else:
         score = score + roll; loop = score < goal
   return score
```

Advantages of while vs for

```
# table of squares to N
seq = []
n = floor(sqrt(N)) + 1
for k in range(n):
    seq.append(k*k)
```

```
# table of squares to N
seq = []
k = 0
while k*k < N:
    seq.append(k*k)
    k = k+1</pre>
```

A for-loop requires that you know where to stop the loop **ahead of time**

A while loop can use complex expressions to check if the loop is done

Advantages of while vs for

Fibonacci numbers:

$$F_0 = 1$$

$$F_1 = 1$$

$$F_n = F_{n-1} + F_{n-2}$$

```
# Table of n Fibonacci nums
fib = [1, 1]
for k in range(2,n):
    fib.append(fib[-1] + fib[-2])
```

Sometimes you do not use the loop variable at all

Table of n Fibonacci nums
fib = [1, 1]
while len(fib) < n:
 fib.append(fib[-1] + fib[-2])</pre>

Do not need to have a loop variable if you don't need one

Difficulties with while

Be careful when you **modify** the loop variable

```
>>> a = [3, 3, 2]
>>> rem3(a)
>>> a
A: [2]
B: [3]
```

C: [3,2]

D: []

E: something else

Difficulties with while

Be careful when you **modify** the loop variable

```
>>> a = [3, 3, 2]
>>> rem3(a)
```

>>> a

A: [2]

B: [3]

C: [3,2] **Correct**

D: []

E: something else

Difficulties with while

Be careful when you modify the loop variable

```
def rem3(lst):
  """Remove all 3's from lst"""
  i = 0
  while i < len(lst):
     # no 3's in lst[0..i-1]
     if lst[i] == 3:
        del lst[i]
                      Stopping
     else:
                     point keeps
        i = i+1
                      changing
```

The stopping condition is not a numerical counter this time. Simplifies code a lot.

Application: Convergence

- How to implement this function?
 def sqrt(c):
 - """Returns the square root of c"""
- Consider the polynomial $f(x) = x^2 c$
 - Value sqrt(c) is a root of this polynomial
- Suggests a use for Newton's Method
 - Start with a guess at the answer
 - Use calculus formula to improve guess

Example: Sqrt(2)

Actual answer: 1.414235624

•
$$x_{n+1} = x_n/2 + c/2x_n$$

- $x_0 = 1$ # Rough guess of sqrt(2)
- $x_1 = 0.5 + 1 = 1.5$
- $x_2 = 0.75 + 2/3 = 1.41666$
- $x_3 = 0.7083 + 2/2.833 = 1.41425$

When Do We Stop?

- We don't know the sqrt(c)
 - This was thing we wanted to compute!
 - So we cannot tell how far off we are
 - But we do know $sqrt(c)^2 = c$
- So square approximation and compare
 - while x*x is not close enough to c
 - while abs(x*x c) > threshold

When Do We Stop?

- We don't know the sqrt(c)
 - This was thing we wanted to compute!
 - So we cannot tell how far off we are
 - But we do know $sqrt(c)^2 = c$
- So square approximation and compare

While-loop computes until the answer **converges**

The Final Result

def sqrt(c,err=1e-6):

"""Returns: sqrt of c with given margin of error.

Preconditions: c and err are numbers > 0"""

$$x = c/2.0$$

while abs(x*x-c) > err:

Get
$$x_{n+1}$$
 from x_n

$$x = x/2.0+c/(2.0*x)$$

return x

Using while-loops Instead of for-loops

Advantages

- Better for modifying data
 - More natural than range
 - Works better with deletion
- Better for convergent tasks
 - Loop until calculation done
 - Exact steps are unknown
- Easier to stop early
 - Just set loop var to False

Disadvantages

- Performance is slower
 - Python optimizes for-loops
 - Cannot optimize while
- Infinite loops more likely
 - Easy to forget loop vars
 - Or get stop condition wrong
- **Debugging** is harder
 - Will see why in later lectures

Optional Exercise

The Game of Pig: A Random Game

- Play progresses clockwise
- On your turn, throw the die:
 - If roll 1: lose turn, score zero
 - Anything else: add it to score
 - Can also roll again (and lose)
 - If stop, score is "banked"
- First person to 100 wins

The Game of Pig: A Random Game

- Play progresses clockwise
- On your turn, throw the die:
 - If roll Easy to write without classes
 - Can also roll again (and lose)

 - If stop, score is "banked"
- First person to 100 wins

Anyt

Designing an AI for Opponent is Easy

The Primary Function

def play(target):

"""Plays a single game of Pig to target score.

Precondition: target is an int > 0"""

Initialize the scores

while no one has reached the target

Play a round for the player

If the player did not reach the target

Play a round for the opponent

Display the results

The Player Round

```
def player_turn():
     Runs a single turn for the player."""
  # while the player has not stopped
     # Roll the die
     # If is a 1
         # Set score to 0 and stop the turn
     # else
                                        Prompt helper
         # Add the to the score
         # Ask the player whether to continue
  # Return the score
```

The Opponent Round

```
def roll_past(goal):
   """Returns: The score from rolling a die until passing goal."""
   loop = True # Keep looping until this is false
   score = 0
   while loop:
      roll = random.randint(1,6)
                                             Look familiar?
      if roll == 1:
         score = 0; loop = False
      else:
         score = score + roll; loop = score < goal
   return score
```
