

## String is a Class; Quoted Text is an Object

- String s = "abc d";
- Indexed characters:

01234

abc d

- s.length() is 5
- s.charAt(2) is 'c'
- s.substring(2) is "c d"
- s.substring(1,3) is "bc"

## String Has a Lot of Useful Methods

- String s = "abc d";
- Indexed characters:

01234

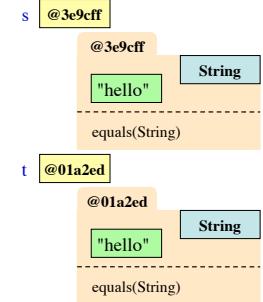

abc d

- s.substring(2,4) is "c " (**NOT "c d"**)
- s.substring(2) is "c d"
- "bcd ".trim() is "bcd"
- (trim beginning and ending blanks)
- s.indexOf("bc") is 1
- (index or position of first occurrence of in "bc" or -1 if none)

- See text pp. 175–181
- Look in CD ProgramLive
- Look at API specs for String

## String Variables Hold Folder Names

- Create two Strings
  - String s = "hello";
  - String t = "hello";
- Do not use `==` to test equality of `s` and `t`
  - `s == t` tests if same object
  - Not useful for Strings
- Use `equals()` instead
  - `s.equals(t)` tests if they have the same text

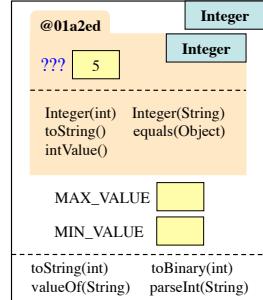

## Containers

- Container:** an object that holds a list of objects
  - But cannot hold primitive values (e.g. `int`, `double`, etc.)!
- Java has several container classes
  - The are all in package `java.util`
  - Generic classes:** type depends on what is contained
  - Put contained type in `<>`
- Example:** `Vector`
  - `Vector<String>`: Vector that holds String objects
  - `Vector<AcornProfile>`: Holds AcornProfile objects
  - `Vector<Vector<String>>`: ????
  - Vector<int>**: NOT ALLOWED!

## Wrappers: Turn Primitives into Objects

- Want `Vector<int>`
  - int is primitive type, not class
  - Need to convert an int value (e.g. 9) into an object
- Integer: a wrapper class**
  - Contains or wraps one value
  - Value cannot be changed: it is *immutable*
- Many useful static features
  - `Integer.MAX_VALUE`
  - `Integer.parseInt(String)`

## Each Primitive Type Has a Wrapper

- When you need to treat a primitive value as an object, then just wrap the value in an object of the wrapper class.

Primitive Type	Wrapper Class
int	Integer
long	Long
float	Float
double	Double
char	Character
boolean	Boolean

### Each wrapper class has:

- Instance methods (e.g. `equals`, constructors, `toString`)
- Static variables and methods (for useful computations)

`Integer k= new Integer(63); int j= k.intValue();`

You don't have to memorize the methods of the wrapper classes. But be aware of them. See Section 5.1 and PLive 5-1 and 5-2 for more.

## Example: Vector

- Create an empty vector instance (of Strings)
 

```
import java.util.Vector;
Vector vec = new Vector<Integer>();
```
- Add some strings to it
 

```
vec.add(new Integer(2)); // Adds 2 at position 0
vec.add(new Integer(7)); // Adds 7 at position 1
vec.add(new Integer(-3)); // Adds -3 at position 2
```
- Get the String at position 1
 

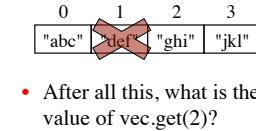

```
vec.get(1) // Function call, gives 7
```
- Search vector for number 5
 

```
vec.indexOf(new Integer(5)) // Not found; gives -1
```

## Vectors Can Add and Remove

- Do the following:

```
import java.util;
Vector vec = new
Vector<String>();
vec.add("abc");
vec.add("def");
vec.add("ghi");
vec.add("jkl");
vec.remove(1);
```

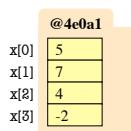

- After all this, what is the value of vec.get(2)?

A: Function gives "abc"  
 B: Function gives "ghi"  
 C: Function gives "jkl"  
 D: I have no clue

## Arrays

- Array:** an object that holds a fixed number of values of **the same type**
- Type of an array is written:  
`<type>[]` (e.g. `int[]`)
- Declare a variable `x` that holds the name of an array of `ints`:  
`<type> <name>;` (e.g., `int[] x;`)
- Elements of array `x` are numbered:  
`0, 1, 2, ..., n - 1`
- To refer to an element of an array:  
`<var>[<index>]` (e.g. `x[3]`)

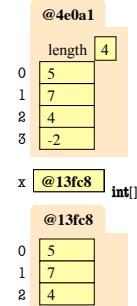

This array contains 4 values of type `int`

`x` @4e0a1 int[]

## Arrays

- Array length is a field of the object `x.length` [not `x.length()`]
- The length field is **final**: it never changes after the array is created
- Length is not part of the array type
  - An `int[]` variable can hold arrays of different lengths at different times
- Declaring `x` does not create array
  - As an object it starts out `null`
  - Need a special new-expression:  
`new <type>[<length>]`  
(e.g. `x = new int[3];`)

## Arrays vs. Vectors vs. Strings

<b>Declaration</b> <code>int[] a;</code> (contains <code>ints</code> )	<b>Declaration</b> <code>Vector&lt;Integer&gt; v;</code> (contains <code>Integers</code> )	<b>Declaration</b> <code>String s;</code> (contains <code>chars</code> )
<b>Creation</b> <code>a = new int[n];</code> (size fixed forever)	<b>Creation</b> <code>v= new Vector&lt;Integer&gt;();</code> (can be resized at will)	<b>Creation</b> <code>s = "foo";</code> (contents fixed forever)
<b>Reference</b> <code>x = a[i];</code>	<b>Reference</b> <code>x= v.get(i);</code>	<b>Reference</b> <code>c = s.charAt(i);</code>
<b>Change</b> <code>a[i] = x;</code>	<b>Change</b> <code>v.set(i, x);</code>	<b>Cannot Change</b>

Variables `a[0], a[1], ...` are at successive locations in memory. Element type can be class or primitive type.

Storage layout unspecified (but really, it is an array). Element type can only be a *class* type.

Storage layout unspecified (but really, it is an array) Element type is always `char`.

## Array Initializers

- Initializing a newly created array:
  - `int[] c= new int[5];` ← create array of 5 ints initialized with default (0)
  - `c[0]= 5; c[1]= 4; c[2]= 7; c[3]= 6; c[4]= 5;` ← assign new values to elements
- Instead, use an array initializer: ← create array of 5 ints and initialize all elements
  - `new int[] { 5, 4, 7, 6, 5 }`

↑  
no size goes here (implied by length of initializer list)  
types must agree with array's type
- In a declaration, short form is available:
  - `int[] c;`
  - `c= new int[] { 5, 4, 7, 6, 5 };`
  - `int[] c= new int[] { 5, 4, 7, 6, 5 };`
  - `int[] c= { 5, 4, 7, 6, 5 };`

} all three do the same thing
