Hard links

Hard links act almost like separate copies of the file, but they point to the same area of the disk, so all changes made to one also affect all other "copies".

Symbolic links

Symbolic link is sort of just a string giving the location of the "master" file(directory). However, if programs try to read/write/execute/access the symbolic link, they get the master file instead.

Creating links - ln

In options src dst — create a link dst pointing to src In options $src_1 \dots src_n$ dstdir — in dstdir create links pointing to $src_1 \dots src_n$ with the same names as $src_1 \dots src_n$

Options:

- -s create symbolic links instead of hard links
- -f overwrite destination if it already exists.
