Spring 2021

Lecture 29

Least Squares

Announcements

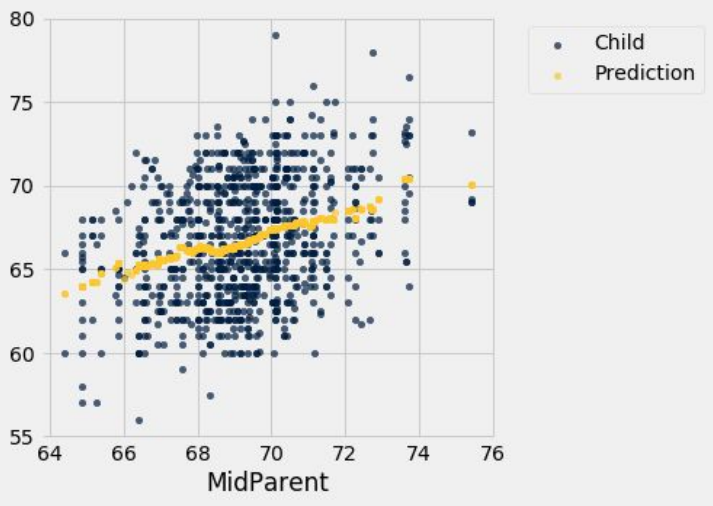
- Prelim 2, April 20, 8:30PM-10PM in Kennedy 116 (here) for Ithaca-resident students, assigned seating
  - Coverage from Lecture 12 - Lecture 26 (Monday)
  - Review sheet and sample exam posted on Canvas.
  - Table of functions included again, allowed a double-sided sheet of notes you make yourself

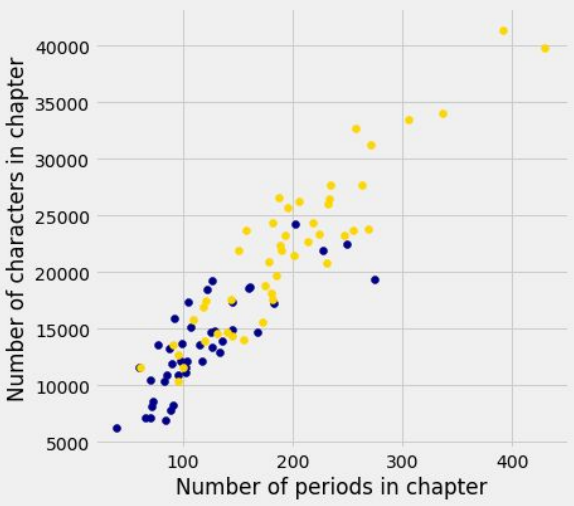
Announcements: Coming up

- HW 5 out, due 4/30
- This Wednesday/Thursday: Lab 8
- Friday 4/23, Monday 4/26: Wellness days, no lecture
- Wednesday 4/28, Thursday 4/29: Lab 9
- Friday 4/30: Project 3 out, Part 1 due 5/7, Part 2 due 5/14
- Labs 5/5, 5/6; 5/12, 5/13 dedicated to working on Project 3.
- Final: May 22.

Prediction

If we have a line describing the relation between two variables, we can make predictions



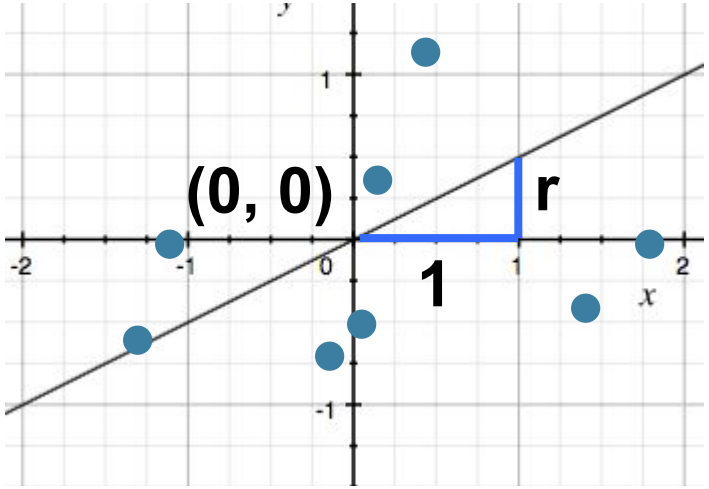


Prediction

- **Problem:** given a known *x* value, predict *y*, where both are in standard units
- **Solution:**
  - Compute correlation coefficient *r*
  - Predict that $y = r * x$
- Why is that a line? (slope = *r*, intercept = 0)
- Why use that line?
  - It is a version of the graph of averages, smoothed to a line

Regression Line Equation

In standard units, the equation of the regression line is:



Fitted value

Observed value

$$y_{(\text{su})} = r \times x_{(\text{su})}$$

Correlation coefficient

Regression Line Equation

In original units, the regression line has this equation:

$$\frac{\text{estimate of } y \ - \ \text{average of } y}{\text{SD of } y} = r \times \frac{\text{the given } x \ - \ \text{average of } x}{\text{SD of } x}$$

y in standard units

x in standard units

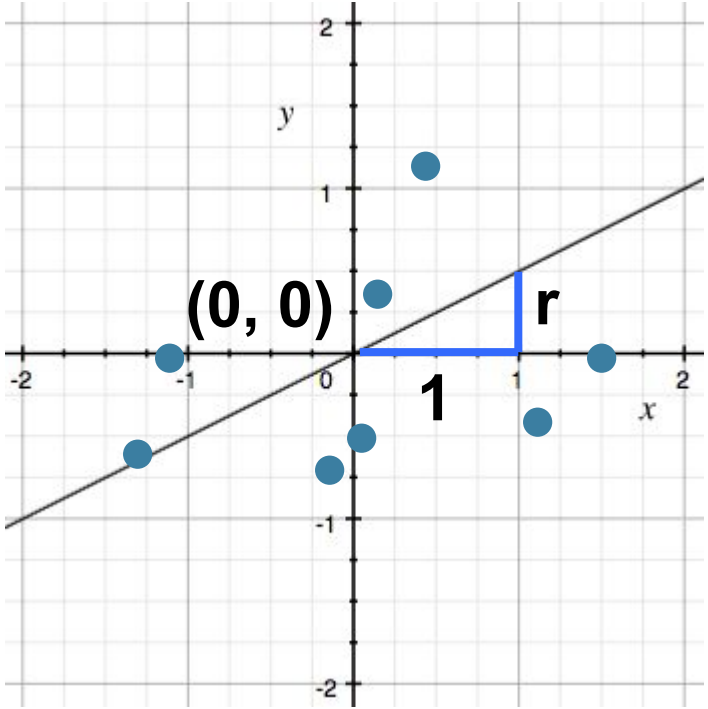
$$y = \text{slope} \times x + \text{intercept}$$

$$\textbf{slope of the regression line} = r \cdot \frac{\text{SD of } y}{\text{SD of } x}$$

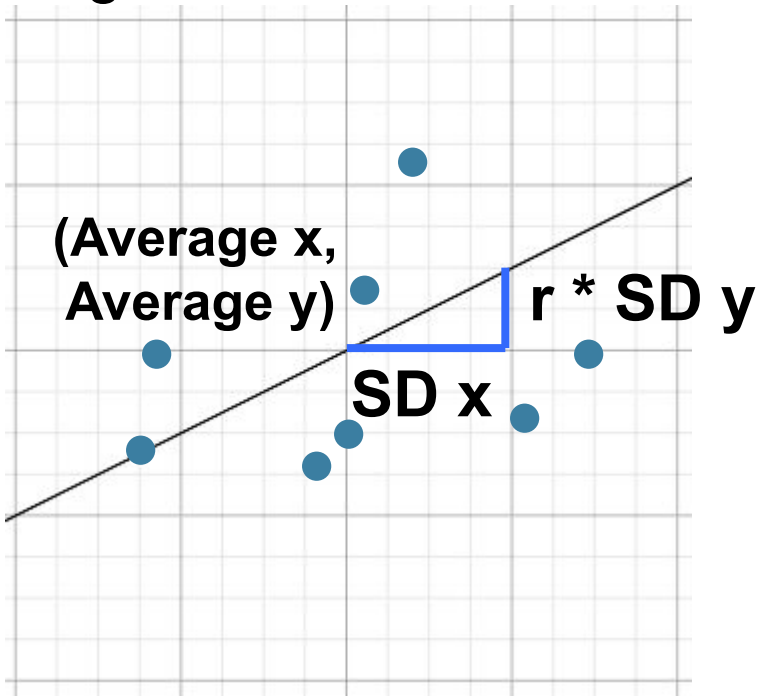
$$\textbf{intercept of the regression line} = \text{average of } y - \text{slope} \cdot \text{average of } x$$

Regression Line

Standard Units



Original Units



(Demo)

Which of these to predict a final exam score?

$y = r * x$

$y = r * x + i$

$y = s * x + i$

None of the above

Abuses of *r*

- Summarizing non-linear data with *r*
- Eliminating outliers to “improve” *r*
- Drawing conclusions about individuals based on data about groups (*ecological* correlations)
- Jumping to conclusions about causality

Correlation is not causation

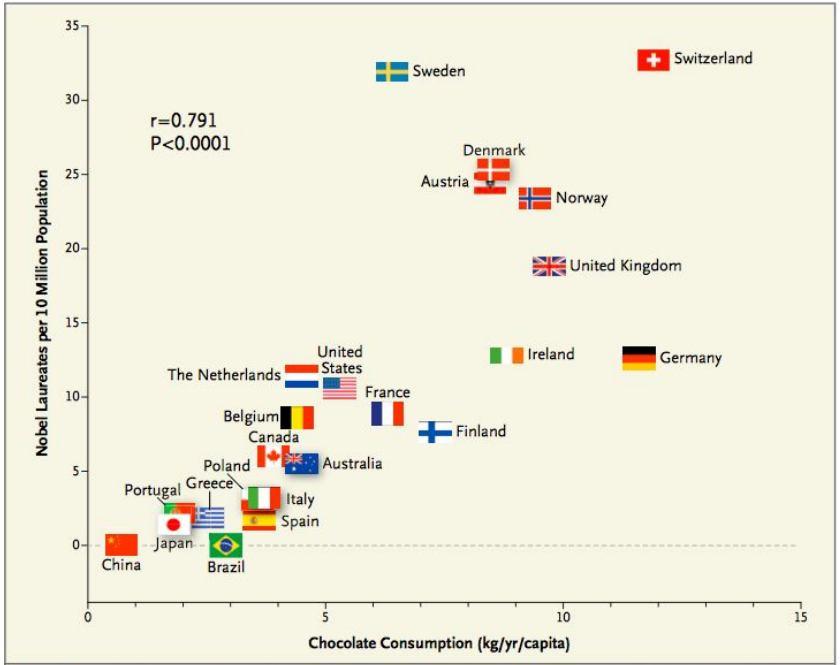


Figure 1. Correlation between Countries' Annual Per Capita Chocolate Consumption and the Number of Nobel Laureates per 10 Million Population.

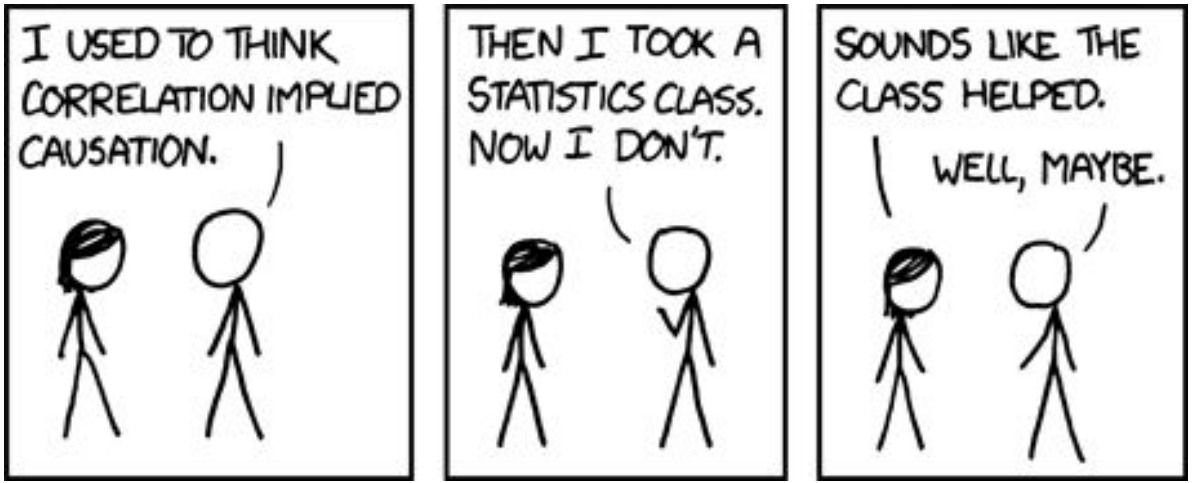
Correlation is not causation



Quantifying Error

Error in Prediction

- How good is the regression line at making predictions?
  - Hard to say for unknown data
  - But easy for data we already have

- **error = actual value − prediction**

(Demo)

Error in Prediction

- How good is the regression line at making predictions?
  - Hard to say for unknown data
  - But easy for data we already have

- **error = actual value − prediction**
- RMSE = root mean square error

  4 3 2 1
- RMSE = root mean square of deviation from prediction

  5 4 3 2 1

(Demo)

RMSE

RMSE = root mean square error

RMSE = std(y) * sqrt(1 - r^2)

- If r = 1, what is RMSE? 0
- If r = 0, what is RMSE? std(y)

Compare regression line to other lines using RMSE...

(Demo)

Line with smallest RMSE?

- SciPy function **`minimize(f)`** returns the value **`x`** that produces the minimum output **`f(x)`** from **`f`**
- Also works for functions that make multiple arguments
- How to use to find best line:
  - Write function **`rmse(a, b)`** that returns the RMSE for line with slope **`a`** and intercept **`b`**
  - Call **`minimize(rmse)`** and get output array $[a_0, b_0]$
  - a_0 is slope and b_0 intercept of line that minimizes RMSE

(Demo)

Regression line

- Regression line has the minimum RMSE of all lines
- Names:
  - Regression line
  - Least squares line
  - “Best fit” line
