

A well-known scientist (some say it was Bertrand Russell) once gave a public lecture on astronomy. He described how the earth orbits around the sun and how the sun, in turn, orbits around the center of a vast collection of stars called our galaxy.

At the end of the lecture, a little old lady at the back of the room got up and said: "What you have told us is rubbish. The world is really a flat plate supported on the back of a giant tortoise." The scientist gave a superior smile before replying, "What is the tortoise standing on?"' 'You're very clever, young man, very clever', said the old lady. 'But it's turtles all the way down!"

## INDUCTION

## Lecture 20

## Overview: Reasoning about Programs

$\square$ Our broad problem: code is unlikely to be correct if we don't have good reasons for believing it works
$\square$ We need clear problem statements
$\square$ And then a rigorous way to convince ourselves that what we wrote solves the problem
$\square$ But reasoning about programs can be hard
$\square$ Especially with recursion, concurrency
$\square$ Today focus on recursion

## Overview: Reasoning about Programs

$\square$ Recursion
$\square$ A programming strategy that solves a problem by reducing it to simpler or smaller instance(s) of the same problem
$\square$ Induction
$\square$ A mathematical strategy for proving statements about natural numbers $0,1,2, \ldots$ (or more generally, about inductively defined objects)
$\square$ They are very closely related
$\square$ Induction can be used to establish the correctness and complexity of programs

## Defining Functions

$\square$ It is often useful to describe a function in different ways
$\square$ Let $S:$ int $\rightarrow$ int be the function where $S(n)$ is the sum of the integers from 0 to $n$. For example,

$$
S(0)=0 \quad S(3)=0+1+2+3=6
$$

$\square$ Definition: iterative form
$\square S(n)=0+1+\ldots+n$

$$
=\sum_{i=0}^{n} i
$$

$\square$ Another characterization: closed form
$-S(n)=n(n+1) / 2$

## Sum of Squares

$\square$ A more complex example
$\square$ Let $S Q:$ int $\rightarrow$ int be the function that gives the sum of the squares of integers from 0 to n :

$$
\begin{aligned}
& S Q(0)=0 \\
& S Q(3)=0^{2}+1^{2}+2^{2}+3^{2}=14
\end{aligned}
$$

$\square$ Definition (iterative form):

$$
S Q(n)=0^{2}+1^{2}+\ldots+n^{2}
$$

$\square$ Is there an equivalent closed-form expression?

## Closed-Form Expression for SQ(n)

$\square$ Sum of integers between 0 through $n$ was $n(n+1) / 2$ which is a quadratic in n (that is, $\mathrm{O}\left(\mathrm{n}^{2}\right)$ )

- Inspired guess: perhaps sum of squares of integers between 0 through $n$ is a cubic in $n$

$\square$ Conjecture: $S Q(n)=a n^{3}+b n^{2}+c n+d$ where $a, b, c, d$ are unknown coefficients
$\square$ How can we find the values of the four unknowns?
$\square$ Idea: Use any 4 values of $n$ to generate 4 linear equations, and then solve

## Finding Coefficients

$$
S Q(n)=0^{2}+1^{2}+\ldots+n^{2}=a n^{3}+b n^{2}+c n+d
$$

$\square$ Use $n=0,1,2,3$
$\square S Q(0)=0 \quad=a \cdot 0+b \cdot 0+c \cdot 0+d$
$\square S Q(1)=1 \quad=a \cdot 1+b \cdot 1+c \cdot 1+d$

$\square S Q(2)=5=a \cdot 8+b \cdot 4+c \cdot 2+d$
$\square S Q(3)=14=a \cdot 27+b \cdot 9+c \cdot 3+d$
$\square$ Solve these 4 equations to get
$\square a=1 / 3$
$b=1 / 2$
$c=1 / 6$
$d=0$

## Is the Formula Correct?

This suggests

$$
\begin{aligned}
S Q(n) & =0^{2}+1^{2}+\ldots+n^{2} \\
& =n^{3} / 3+n^{2} / 2+n / 6 \\
& =n(n+1)(2 n+1) / 6
\end{aligned}
$$

$\square$ Question: Is this closed-form solution true for all n?
$\square$ Remember, we only used $n=0,1,2,3$ to determine these coefficients
$\square$ We do not know that the closed-form expression is valid for other values of $n$

## One Approach

$\square$ Try a few other values of $n$ to see if they work.
$\square$ Try $\mathrm{n}=5: \quad \mathrm{SQ}(\mathrm{n})=0+1+4+9+16+25=55$
$\square$ Closed-form expression: 5•6•11/6=55
$\square$ Works!
$\square$ Try some more values...
$\square$ We can never prove validity of the closed-form solution for all values of $n$ this way, since there are an infinite number of values of $n$

## A Recursive Definition

$\square$ To solve this problem, let's express $S Q(n)$ in a different way:
$\square S Q(n)=0^{2}+1^{2}+\ldots+(n-1)^{2}+n^{2}$

- The part in the box is just $S Q(n-1)$
$\square$ This leads to the following recursive definition
$\square S Q(0)=0$
Base Case
$\square S Q(n)=S Q(n-1)+n^{2}, n>0$
$\square$ Thus,
$\square \mathrm{SQ}(4)=\mathrm{SQ}(3)+4^{2}=\mathrm{SQ}(2)+3^{2}+4^{2}=\mathrm{SQ}(1)+2^{2}+3^{2}+$ $4^{2}=S Q(0)+1^{2}+2^{2}+3^{2}+4^{2}=0+1^{2}+2^{2}+3^{2}+4^{2}$

## Are These Two Functions Equal?

$\square \mathrm{SQ}_{\mathrm{r}}(\mathrm{r}=$ recursive $)$

$$
\begin{aligned}
& S Q_{r}(0)=0 \\
& S Q_{r}(n)=S Q_{r}(n-1)+n^{2}, n>0
\end{aligned}
$$

$\square S Q_{c}(c=$ closed-form)

$$
S Q_{c}(n)=n(n+1)(2 n+1) / 6
$$

## Induction over Integers

$\square$ To prove that some property $\mathrm{P}(\mathrm{n})$ holds for all integers $n \geq 0$,

1. Basis: Show that $P(0)$ is true
2. Induction Step: Assuming that $P(k)$ is true for an unspecified integer $k$, show that $P(k+1)$ is true
$\square$ Conclusion: Because we could have picked any k, we conclude that $P(n)$ holds for all integers $n \geq 0$

## Dominos

$\square$ Assume equally spaced dominos, and assume that spacing between dominos is less than domino length
$\square$ How would you argue that all dominos would fall?
$\square$ Dumb argument:

- Domino 0 falls because we push it over
- Domino 0 hits domino 1, therefore domino 1 falls
- Domino 1 hits domino 2, therefore domino 2 falls
- Domino 2 hits domino 3, therefore domino 3 falls
- ...
$\square$ Is there a more compact argument we can make?

## Better Argument

$\square$ Argument:

- Domino 0 falls because we push it over (Base Case or Basis)
- Assume that domino k falls over (Induction Hypothesis)
- Because domino k's length is larger than inter-domino spacing, it will knock over domino k+1 (Inductive Step)
$\square$ Because we could have picked any domino to be the $\mathrm{k}^{\text {th }}$ one, we conclude that all dominos will fall over (Conclusion)
$\square$ This is an inductive argument
$\square$ This version is called weak induction
$\square$ There is also strong induction (later)
$\square$ Not only is this argument more compact, it works for an arbitrary number of dominoes!

## $S Q_{r}(n)=S Q_{c}(n)$ for all $n$ ?

$\square$ Define $P(n)$ as $S Q_{r}(n)=S Q_{c}(n)$

$\square$ Prove P(0)
$\square$ Assume $P(k)$ for unspecified $k$, and then prove $P(k+1)$ under this assumption

## Proof (by Induction)

$$
\begin{aligned}
& \operatorname{Recall:}^{S Q_{r}(0)=0} \\
& S Q_{r}(n)=S Q_{r}(n-1)+n^{2}, \quad n>0 \\
& S Q_{c}(n)=n(n+1)(2 n+1) / 6
\end{aligned}
$$

$\square$ Let $P(n)$ be the proposition that $S Q_{r}(n)=S Q_{c}(n)$
$\square$ Basis: $P(0)$ holds because $S Q_{r}(0)=0$ and $S Q_{c}(0)=0$ by definition
$\square$ Induction Hypothesis: Assume $S Q_{r}(k)=S Q_{c}(k)$

- Inductive Step:

$$
\begin{aligned}
S Q_{r}(k+1) & =S Q_{r}(k)+(k+1)^{2} & & \text { by definition of } S Q_{r}(k+1) \\
& =S Q_{c}(k)+(k+1)^{2} & & \text { by the Induction } H y p o t h e s i s \\
& =k(k+1)(2 k+1) / 6+(k+1)^{2} & & \text { by definition of } S Q_{c}(k) \\
& =(k+1)(k+2)(2 k+3) / 6 & & \text { algebra } \\
& =S Q_{c}(k+1) & & \text { by definition of } S Q_{c}(k+1)
\end{aligned}
$$

$\square$ Conclusion: $S Q_{r}(n)=S Q_{c}(n)$ for all $n \varepsilon 0$

## Another Example

$\square$ Prove that $0+1+\ldots+n=n(n+1) / 2$
$\square$ Basis: Obviously holds for $\mathrm{n}=0$

- Induction Hypothesis: Assume 0+1+... $+\mathrm{k}=\mathrm{k}(\mathrm{k}+1) / 2$
$\square$ Inductive Step:

$$
\begin{aligned}
0+1+\ldots+(k+1) & =[0+1+\ldots+k]+(k+1) & & \text { by def } \\
& =k(k+1) / 2+(k+1) & & \text { by I.H. } \\
& =(k+1)(k+2) / 2 & & \text { algebra }
\end{aligned}
$$

- Conclusion: $0+1+\ldots+n=n(n+1) / 2$ for all $n \geq 0$

## A Note on Base Cases

$\square$ Sometimes we are interested in showing some proposition is true for integers $\geq b$
$\square$ Intuition: we knock over domino $b$, and dominoes in front get knocked over; not interested in $0,1, \ldots,(b-1)$

- In general, the base case in induction does not have to be 0
$\square$ If base case is some integer $b$
- Induction proves the proposition for $n=b, b+1, b+2, \ldots$
- Does not say anything about $n=0,1, \ldots, b-1$

## Weak Induction: Nonzero Base Case

$\square$ Claim: You can make any amount of postage above $8 申$ with some combination of $3 \phi$ and $5 \phi$ stamps
$\square$ Basis: True for $8 ¢$ : $8=3+5$
$\square$ Induction Hypothesis: Suppose true for some k $\geq 8$

- Inductive Step:
- If used a $5 \phi$ stamp to make $k$, replace it by two $3 \phi$ stamps. Get k+1.
- If did not use a $5 \phi$ stamp to make $k$, must have used at least three $3 \phi$ stamps. Replace three $3 \phi$ stamps by two $5 \phi$ stamps. Get $k+1$.
$\square$ Conclusion: Any amount of postage above $8 \phi$ can be made with some combination of $3 \phi$ and $5 \phi$ stamps

## What are the "Dominos"?

$\square$ In some problems, it can be tricky to determine how to set up the induction
$\square$ This is particularly true for geometric problems that can be attacked using induction

## A Tiling Problem

$\square$ A chessboard has one square cut out of it
$\square$ Can the remaining board be tiled using tiles of the shape shown in the picture (rotation allowed)?
$\square$ Not obvious that we can use induction!

## Proof Outline

$\square$ Consider boards of size $2^{n} \times 2^{n}$ for $n=1,2, \ldots$
$\square$ Basis: Show that tiling is possible for $2 \times 2$ board
$\square$ Induction Hypothesis: Assume the $2^{k} \times 2^{k}$ board can be tiled

- Inductive Step: Using I.H. show that the $2^{k+1} \times 2^{k+1}$ board can be tiled
$\square$ Conclusion: Any $2^{n} \times 2^{n}$ board can be tiled, $n=1,2, \ldots$
$\square$ Our chessboard ( $8 \times 8$ ) is a special case of this argument
$\square$ We will have proven the $8 \times 8$ special case by solving a more general problem!

## Basis

$\square$ The $2 \times 2$ board can be tiled regardless of which one of the four pieces has been omitted

$2 \times 2$ board

## $4 \times 4$ Case

$\square$ Divide the $4 \times 4$ board into four $2 \times 2$ sub-boards
$\square$ One of the four sub-boards has the missing piece

- By the I.H., that sub-board can be tiled since it is a $2 \times 2$ board with a missing piece
$\square$ Tile center squares of three remaining sub-boards as shown
- This leaves three $2 \times 2$ boards, each with a missing piece
- We know these can be tiled by the Induction Hypothesis

## $2^{k+1} \times 2^{k+1}$ case

$\square$ Divide board into four sub-boards and tile the center squares of the three complete sub-boards
$\square$ The remaining portions of the sub-boards can be tiled by the I.H. (which assumes we can tile $2^{k} \times 2^{k}$ boards)

## When Induction Fails

$\square$ Sometimes an inductive proof strategy for some proposition may fail
$\square$ This does not necessarily mean that the proposition is wrong

- It may just mean that the particular inductive strategy you are using is the wrong choice
$\square$ A different induction hypothesis (or a different proof strategy altogether) may succeed

## Tiling Example (Poor Strategy)

$\square$ Let's try a different induction strategy
$\square$ Proposition
$\square$ Any $\mathrm{n} \times \mathrm{n}$ board with one missing square can be tiled
$\square$ Problem

- A $3 \times 3$ board with one missing square has 8 remaining squares, but our tile has 3 squares; tiling is impossible
$\square$ Thus, any attempt to give an inductive proof of this proposition must fail
$\square$ Note that this failed proof does not tell us anything about the $8 \times 8$ case

## A Seemingly Similar Tiling Problem

$\square$ A chessboard has opposite corners cut out of it. Can the remaining board be tiled using tiles of the shape shown in the picture (rotation allowed)?
$\square$ Induction fails here. Why? (Well...for one thing, this board can't be tiled with dominos.)

## Strong Induction

$\square$ We want to prove that some property P holds for all n
$\square$ Weak induction

- $P(0)$ : Show that property $P$ is true for 0
- $P(k) \Rightarrow P(k+1)$ : Show that if property $P$ is true for $k$, it is true for $k+1$
- Conclude that $P(n)$ holds for all $n$
$\square$ Strong induction
- $P(0)$ : Show that property $P$ is true for 0
- $P(0)$ and $P(1)$ and $\ldots$ and $P(k) \Rightarrow P(k+1)$ : show that if $P$ is true for numbers less than or equal to $k$, it is true for $k+1$
- Conclude that $P(n)$ holds for all $n$
$\square$ Both proof techniques are equally powerful

## Conclusion

$\square$ Induction is a powerful proof technique
$\square$ Recursion is a powerful programming technique
$\square$ Induction and recursion are closely related
$\square$ We can use induction to prove correctness and complexity results about recursive programs
