

SEARCHING, SORTING, AND ASYMPTOTIC COMPLEXITY

CS2110 – Spring 2015
Lecture 10

Merge two adjacent sorted segments

2

```

/** Sort b[h..k]. Precondition: b[h..t] and b[t+1..k] are sorted. */
public static merge(int[] b, int h, int t, int k) {
    Copy b[h..t] into another array c;
    Copy values from c and b[t+1..k] in ascending order into b[h..]
}

```

We leave you to write this method. It is not difficult. Just have to move values from c and $b[t+1..k]$ into b in the right order, from smallest to largest. Runs in time $O(k+1-h)$

Mergesort

3

```

/** Sort b[h..k] */
public static mergesort(int[] b, int h, int k) {
    if (size b[h..k] < 2)
        return;
    int t = (h+k)/2;
    mergesort(b, h, t);
    mergesort(b, t+1, k);
    merge(b, h, t, k);
}

```

merge is $O(k+1-h)$

This is $O(n \log n)$ for an initial array segment of size n

But space is $O(n)$ also!

Mergesort

4

```

/** Sort b[h..k] */
public static mergesort(
    int[] b, int h, int k) {
    if (size b[h..k] < 2)
        return;
    int t = (h+k)/2;
    mergesort(b, h, t);
    mergesort(b, t+1, k);
    merge(b, h, t, k);
}

```

Runtime recurrence

$T(n)$: time to sort array of size n

$T(1) = 1$

$T(n) = 2T(n/2) + O(n)$

Can show by induction that $T(n)$ is $O(n \log n)$

Alternatively, can see that $T(n)$ is $O(n \log n)$ by looking at tree of recursive calls

QuickSort versus MergeSort

5

<pre> /** Sort b[h..k] */ public static void QS (int[] b, int h, int k) { if (k - h < 1) return; int j = partition(b, h, k); QS(b, h, j-1); QS(b, j+1, k); } </pre>	<pre> /** Sort b[h..k] */ public static void MS (int[] b, int h, int k) { if (k - h < 1) return; MS(b, h, (h+k)/2); MS(b, (h+k)/2 + 1, k); merge(b, h, (h+k)/2, k); } </pre>
--	---

One processes the array then recurses.
One recurses then processes the array.

Readings, Homework

6

- Textbook: Chapter 4
- Homework:
 - Recall our discussion of linked lists and A2.
 - What is the worst case complexity for appending an items on a linked list? For testing to see if the list contains X ? What would be the best case complexity for these operations?
 - If we were going to talk about complexity (speed) for operating on a list, which makes more sense: worst-case, average-case, or best-case complexity? Why?

What Makes a Good Algorithm?

7

Suppose you have two possible algorithms or ADT implementations that do the same thing; which is *better*?

What do we mean by *better*?

- Faster?
- Less space?
- Easier to code?
- Easier to maintain?
- Required for homework?

How do we measure time and space of an algorithm?

Basic Step: One “constant time” operation

8

Basic step:

- Input/output of scalar value
 - Access value of scalar variable, array element, or object field
 - assign to variable, array element, or object field
 - do one arithmetic or logical operation
 - method call (not counting arg evaluation and execution of method body)
- **If-statement:** number of basic steps on branch that is executed
 - **Loop:** (number of basic steps in loop body) * (number of iterations) –also bookkeeping
 - **Method:** number of basic steps in method body (include steps needed to prepare stack-frame)

Counting basic steps in worst-case execution

9

Linear Search

Let $n = b.length$

```
/** return true iff v is in b */
static boolean find(int[] b, int v) {
    for (int i = 0; i < b.length; i++) {
        if (b[i] == v) return true;
    }
    return false;
}
```

worst-case execution

basic step	# times executed
$i = 0;$	1
$i < b.length$	$n+1$
$i++$	n
$b[i] == v$	n
return true	0
return false	1
Total	$3n + 3$

We sometimes simplify counting by counting only important things. Here, it's the number of array element comparisons $b[i] == v$. that's the number of loop iterations: n .

Sample Problem: Searching

10

Second solution: Binary Search

inv:
 $b[0..h] \leq v < b[k..]$

Number of iterations (always the same):
 $\sim \log b.length$
Therefore,
 $\log b.length$
array comparisons

```
/** b is sorted. Return h satisfying
    b[0..h] <= v < b[h+1..] */
static int bsearch(int[] b, int v) {
    int h = -1;
    int k = b.length;
    while (h+1 != k) {
        int e = (h+k)/2;
        if (b[e] <= v) h = e;
        else k = e;
    }
    return h;
}
```

What do we want from a definition of “runtime complexity”?

11

1. Distinguish among cases for large n , not small n
2. Distinguish among important cases, like
 - $n*n$ basic operations
 - n basic operations
 - $\log n$ basic operations
 - 5 basic operations
3. Don't distinguish among trivially different cases.
 - 5 or 50 operations
 - $n, n+2$, or 4n operations

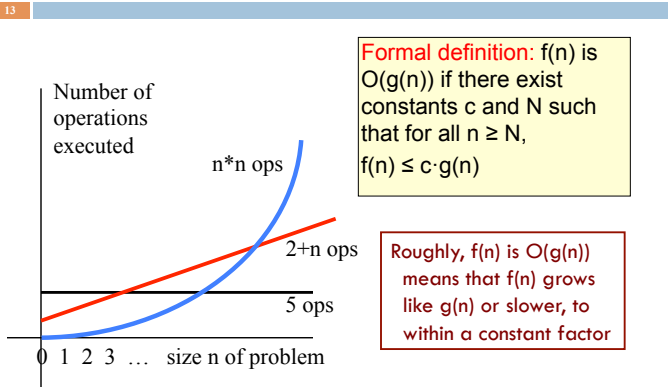

Definition of $O(\dots)$

12

Formal definition: $f(n)$ is $O(g(n))$ if there exist constants c and N such that for all $n \geq N$, $f(n) \leq c \cdot g(n)$

What do we want from a definition of "runtime complexity"?

Prove that $(n^2 + n)$ is $O(n^2)$

Formal definition: $f(n)$ is $O(g(n))$ if there exist constants c and N such that for all $n \geq N$, $f(n) \leq c \cdot g(n)$

Example: Prove that $(n^2 + n)$ is $O(n^2)$

$$\begin{aligned} f(n) &= \text{<definition of } f(n)\text{>} \\ &= n^2 + n \\ &\leq \text{<for } n \geq 1\text{>} \\ &= n^2 + n^2 \\ &= \text{<arith>} \\ &= 2 \cdot n^2 \\ &= \text{<choose } g(n) = n^2\text{>} \\ &= 2 \cdot g(n) \end{aligned}$$

Choose $N = 1$ and $c = 2$

Prove that $100n + \log n$ is $O(n)$

Formal definition: $f(n)$ is $O(g(n))$ if there exist constants c and N such that for all $n \geq N$, $f(n) \leq c \cdot g(n)$

$$\begin{aligned} f(n) &= \text{<put in what } f(n) \text{ is>} \\ &= 100n + \log n \\ &\leq \text{<We know } \log n \leq n \text{ for } n \geq 1\text{>} \\ &= 100n + n \\ &= \text{<arith>} \\ &= 101n \\ &= \text{<}g(n) = n\text{>} \\ &= 101g(n) \end{aligned}$$

Choose $N = 1$ and $c = 101$

$O(\dots)$ Examples

Let $f(n) = 3n^2 + 6n - 7$

- $f(n)$ is $O(n^2)$
- $f(n)$ is $O(n^3)$
- $f(n)$ is $O(n^4)$
- ...

$p(n) = 4n \log n + 34n - 89$

- $p(n)$ is $O(n \log n)$
- $p(n)$ is $O(n^2)$

$h(n) = 20 \cdot 2^n + 40n$

- $h(n)$ is $O(2^n)$

$a(n) = 34$

- $a(n)$ is $O(1)$

Only the *leading term* (the term that grows most rapidly) matters

If it's $O(n^2)$, it's also $O(n^3)$ etc! However, we always use the smallest one

Problem-size examples

Suppose a computer can execute 1000 operations per second; how large a problem can we solve?

alg	1 second	1 minute	1 hour
$O(n)$	1000	60,000	3,600,000
$O(n \log n)$	140	4893	200,000
$O(n^2)$	31	244	1897
$3n^2$	18	144	1096
$O(n^3)$	10	39	153
$O(2^n)$	9	15	21

Commonly Seen Time Bounds

$O(1)$	constant	excellent
$O(\log n)$	logarithmic	excellent
$O(n)$	linear	good
$O(n \log n)$	$n \log n$	pretty good
$O(n^2)$	quadratic	OK
$O(n^3)$	cubic	maybe OK
$O(2^n)$	exponential	too slow

Worst-Case/Expected-Case Bounds

19

May be difficult to determine time bounds for all imaginable inputs of size n

Simplifying assumption #4:

Determine number of steps for either

- ❑ worst-case or
- ❑ expected-case or average case

- **Worst-case**
 - Determine how much time is needed for the *worst possible* input of size n
- **Expected-case**
 - Determine how much time is needed *on average* for all inputs of size n

Worst-Case Analysis of Searching

21

```
Linear Search
// return true iff v is in b
static bool find(int[] b, int v) {
    for (int x : b) {
        if (x == v) return true;
    }
    return false;
}
```

worst-case time: $O(n)$

```
Binary Search
// Return h that satisfies
// b[0..h] <= v < b[h+1..]
static bool bsearch(int[] b, int v) {
    int h = -1; int t = b.length;
    while (h != t-1) {
        int e = (h+t)/2;
        if (b[e] <= v) h = e;
        else t = e;
    }
}
```

Always takes $\sim(\log n + 1)$ iterations.
Worst-case and expected times:
 $O(\log n)$

Comparison of linear and binary search

23

Simplifying Assumptions

20

Use the **size** of the input rather than the input itself – n

Count the number of “basic steps” rather than computing exact time

Ignore multiplicative constants and small inputs (order-of, big-O)

Determine number of steps for either

- ❑ worst-case
- ❑ expected-case

These assumptions allow us to analyze algorithms effectively

Comparison of linear and binary search

22

Analysis of Matrix Multiplication

24

Multiply n -by- n matrices A and B :

Convention, matrix problems measured in terms of n , the number of rows, columns

- Input size is really $2n^2$, not n
- Worst-case time: $O(n^3)$
- Expected-case time: $O(n^3)$

```
for (i = 0; i < n; i++)
    for (j = 0; j < n; j++) {
        c[i][j] = 0;
        for (k = 0; k < n; k++)
            c[i][j] += a[i][k]*b[k][j];
    }
```

Remarks

25

Once you get the hang of this, you can quickly zero in on what is relevant for determining asymptotic complexity

- Example: you can usually ignore everything that is not in the innermost loop. Why?

One difficulty:

- Determining runtime for recursive programs
Depends on the depth of recursion

Why bother with runtime analysis?

26

Computers so fast that we can do whatever we want using simple algorithms and data structures, right?

Not really – data-structure/algorithm improvements can be a very big win

Scenario:

- A runs in n^2 msec
- A' runs in $n^2/10$ msec
- B runs in $10n \log n$ msec

Problem of size $n=10^3$

- A: 10^3 sec \approx 17 minutes
- A': 10^2 sec \approx 1.7 minutes
- B: 10^2 sec \approx 1.7 minutes

Problem of size $n=10^6$

- A: 10^9 sec \approx 30 years
- A': 10^8 sec \approx 3 years
- B: $2 \cdot 10^5$ sec \approx 2 days

1 day = 86,400 sec \approx 10^5 sec

1,000 days \approx 3 years

Algorithms for the Human Genome

27

Human genome
= 3.5 billion nucleotides
 \sim 1 Gb

@1 base-pair
instruction/ μ sec

- $n^2 \rightarrow$ 388445 years
- $n \log n \rightarrow$ 30.824 hours
- $n \rightarrow$ 1 hour

Limitations of Runtime Analysis

28

Big-O can hide a very large constant

- Example: selection
- Example: small problems

The specific problem you want to solve may not be the worst case

- Example: Simplex method for linear programming

Your program may not be run often enough to make analysis worthwhile

- Example: one-shot vs. every day
- You may be analyzing and improving the wrong part of the program
- Very common situation
- Should use profiling tools

What you need to know / be able to do

29

- Know the definition of $f(n)$ is $O(g(n))$
- Be able to prove that some function $f(n)$ is $O(g(n))$. The simplest way is as done on two slides.
- Know worst-case and average (expected) case $O(\dots)$ of basic searching/sorting algorithms: linear/binary search, partition alg of Quicksort, insertion sort, selection sort, quicksort, merge sort.
- Be able to look at an algorithm and figure out its worst case $O(\dots)$ based on counting basic steps or things like array-element swaps/

Lower Bound for Comparison Sorting

30

Goal: Determine minimum time required to sort n items

Note: we want worst-case, not best-case time

- Best-case doesn't tell us much. E.g. Insertion Sort takes $O(n)$ time on already-sorted input
- Want to know worst-case time for best possible algorithm

How can we prove anything about the best possible algorithm?

- Want to find characteristics that are common to all sorting algorithms
- Limit attention to comparison-based algorithms and try to count number of comparisons

Comparison Trees

31

- Comparison-based algorithms make decisions based on comparison of data elements
- Gives a *comparison tree*
- If algorithm fails to terminate for some input, comparison tree is infinite
- Height of comparison tree represents *worst-case number of comparisons* for that algorithm
- Can show: *Any correct comparison-based algorithm must make at least $n \log n$ comparisons in the worst case*

Lower Bound for Comparison Sorting

32

- Say we have a correct comparison-based algorithm
- Suppose we want to sort the elements in an array $b[]$
- Assume the elements of $b[]$ are distinct
- Any permutation of the elements is initially possible
- When done, $b[]$ is sorted
- *But the algorithm could not have taken the same path in the comparison tree on different input permutations*

Lower Bound for Comparison Sorting

33

How many input permutations are possible? $n! \sim 2^{n \log n}$

For a comparison-based sorting algorithm to be correct, it must have at least that many leaves in its comparison tree

To have at least $n! \sim 2^{n \log n}$ leaves, it must have height at least $n \log n$ (since it is only binary branching, the number of nodes at most doubles at every depth)

Therefore its longest path must be of length at least $n \log n$, and that is its worst-case running time
