Prelim 1
CS 2110, October 1, 2015, 5:30 PM

The exam is closed book and closed notes. Do not begin until instructed.

You have 90 minutes. Good luck!

Write your name and Cornell NetID at the top of every page! There are 5 questions on 9 numbered pages, front and back. Check that you have all the pages. When you hand in your exam, make sure your booklet is still stapled together. If not, please use our stapler to reattach all your pages!

We have scrap paper available. If you do a lot of crossing out and rewriting, you might want to write code on scrap paper first and then copy it to the exam, so that we can make sense of what you handed in.

Write your answers in the space provided. Ambiguous answers will be considered incorrect. You should be able to fit your answers easily into the space provided.

In some places, we have abbreviated or condensed code to reduce the number of pages that must be printed for the exam. In others, code has been obfuscated to make the problem more difficult. This does not mean that its good style.

0. Name 1 point

Ensure that your name and NetID is written on every page of this exam.
1. **True / False** (20 points)

**a)** If a is null, evaluation of 
"" + a results in a **NullPointerException**.

**b)** Every Java class except Object extends **exactly** one other Java class.

**c)** boolean[] is a primitive type.

**d)** If class A defines a method with the signature public boolean equals(Object), we say that class A has **overloaded** method equals.

**e)** If class A defines a method with the signature public boolean equals(A), we say that class A has **overridden** method equals.

**f)** Space for a local variable declared in an if-statement is allocated only if the if-condition is true.

**g)** If class B extends abstract class A, then the statement A o= new B(); is illegal.

**h)** Let s be a String variable. Suppose s is null and assertions are enabled. Then, execution of assert s.length() > 0; results in an assertion error (as opposed to some other error).

**i)** Execution of C ob= new C(5); stores the whole new object in ob.

**j)** The statement List<String> b= new List<String>(); is illegal because interfaces cannot be instantiated.

**k)** If class C declares a static method m() and a non-static field name, then m() cannot access name using the this keyword.

**l)** If a local variable f in method m() has the same name as a field, and there is no setter method for field f, the field cannot be accessed within m().

**m)** Execution of Time[] t= new Time[3]; stores in t a pointer to an array that contains pointers to three newly created Time objects.

**n)** If abstract class A contains abstract method m(), and class B extends A but does not implement method m(), then B must also be abstract.

**o)** A doubly linked list allows us to access any value in the list in constant time.

**p)** The only reason to make a class abstract is so that you can put abstract methods in it.

**q)** If classes B and C both extend A, then the statement C c = (C) new B(); is legal.

**r)** Within a constructor, one can explicitly call a constructor in the superclass using the name of the superclass.

**s)** Suppose v points at an object. Execution of v= null; deletes the object to which v points.

**t)** If class Dog extends class Animal and a is declared to be type Animal, then Dog d= (Dog) a; will compile but might result in an exception at runtime.
2. **Short Answer** (36 points)

(a) (4 points) Consider the following code segment, note that (int)'a' is 97, (int)'b' is 98, and (char)99 is 'c'. Execute the segment, writing each value printed to the right of the corresponding println statement.

```java
c char a = 'a';
String b = "b";
int c = 99;
System.out.println(a + b + c);
System.out.println(a + b + (char) c);
System.out.println(c + a + b);
System.out.println(b + a + c);
```

(b) (8 points) A program segment that is supposed to store into \(s\) the sum of values in \(b[h..k]\) has the following precondition and postcondition:

Precondition: \( b \)

\[
\begin{array}{c}
\text{unknown} \\
\text{h} \\
\text{unknown} \\
\text{k}
\end{array}
\]

Postcondition: \( b \)

\[
\begin{array}{c}
\text{s = sum of b[h..k]} \\
\text{h} \\
\text{unknown} \\
\text{i} \\
\text{unknown} \\
\text{k}
\end{array}
\]

A loop with initialization will be written for this problem, using this loop invariant: \(s\) is the sum of \(b[i..k]\), as shown as the the diagram below.

```
Invariant: \( b \)

\[
\begin{array}{c}
\text{unknown} \\
\text{h} \\
\text{unknown} \\
\text{i} \\
\text{unknown} \\
\text{s = sum of these elements} \\
\text{k}
\end{array}
\]
```

Answer the following four questions, which gives you all the parts for the loop. Be extremely careful! Do not simply write the loop you are thinking of; use the invariant shown above.

(i) What initial assignment to \(s\) and \(i\) makes the invariant true?

(ii) What condition along with the invariant implies the postcondition?

(iii) In writing the body of the loop, how do you make progress toward termination?

(iv) In writing the body of the loop, how do you keep the invariant true while making progress toward termination?
(c) (6 points) Indicate which of the following three statements about linked lists are true. Assume you have direct access only to the head of a singly linked list or the head and tail of a doubly linked list. Circle all that are true.

(i) Finding the largest element in a sorted doubly linked list takes constant time.

(ii) Inserting a value in the middle of a doubly linked list takes constant time.

(iii) Inserting a value after the fourth element of a singly linked list takes time proportional to the length of the list.

(d) (6 points) Consider class A, below. Write down the statements S1, S2, S3, S4, S5, and S6 that are executed, in the order they are executed, for the following procedure calls:

1. first(3); Statements executed:

2. first(0); Statements executed:

3. first(6); Statements executed:

```java
public class A {
    public static void first(int i) {
        second(i);
        S1;
    }

    public static void second(int i) {
        S2;
        try {
            int b = 5/i;
            S3;
            if (i == 6) throw new Exception();
            S4;
        } catch (ArithmeticException e) {
            S5;
        }
        S6
    }
}
```

(e) (4 points) Write down the steps in executing a procedure call.
(f) (4 points) Consider the following classes.

```java
class C {
    public String toString() {
        return "I'm a C";
    }
}
class B extends C {
    public String toString() {
        return "I'm a B";
    }
    public static void main(String[] args) {
        B b= new B(); // Suppose the value stored in b is B@12
        C c= b;
        Object o= b;
        System.out.println(b.toString());
        System.out.println(c.toString());
        System.out.println(o.toString());
    }
}
```

What is printed to the console when running class B as an application?

(g) (4 points) Consider the following class.

```java
public class Suit {
    public static final Suit CLUBS= new Suit();
    public static final Suit SPADES= new Suit();
    public static final Suit HEARTS= new Suit();
    public static final Suit DIAMONDS= new Suit();
    private Suit() {} 
}
```

Is there a better way to represent Suits in Java? If so, rewrite class Suit below in that way. If not, explain briefly why the above class is the best way to represent Suits.
3. **Testing** (16 points)

(a) **8 points** Consider the following code, which computes the median of an array of `ints`. Recall that the median of a collection is the “middle” value if the collection has an odd number of elements or the arithmetic mean of two “middle” values otherwise.

```java
/** Return the median value in arr
 * Precondition: arr is not null and arr.length >= 1
 */
public static int median(int[] arr) {
    int n= arr.length / 2;
    // if arr has an odd number of elements
    if (n % 2 != 0)
        return arr[n];
    // n has an even number of elements
    return(arr[n - 1] + arr[n]) / 2;
}
```

• Unfortunately this code has a serious bug. Write a test to illustrate the bug:

```java
@Test
def testMedian()
{
}
```

• Modify the precondition so the method meets its specification.
(b) 8 points Consider the following code, which computes the value of the first argument raised to the value of the second.

```java
/** Return a^n
 * Precondition: n >= 0
 */
public static int power(int a, int n) {
    // if n is 0
    if (n == 0) return 1;
    // n > 0
    return power(a * a, n / 2);
}
```

- Unfortunately this code also has a serious bug. Write a test to illustrate the bug:

```java
@Test
public void testPower() {
}
```

- Modify the code so the method meets its specification:

```java
/** Return a^n
 * Precondition: n >= 0
 */
public static int power(int a, int n) {

}
```
Reference: Java Collections

Following is a reference to selected classes (unshaded) and interfaces (shaded) from the Collections library, as well as the most important methods defined in the interfaces. This information may be useful in completing the exercise on the opposite page.

interface Collection<E> {
    boolean add(E);
    void clear();
    boolean contains(Object);
    boolean equals(Object);
    boolean isEmpty();
    boolean remove(Object);
    int size();
    ...
}

interface Set<E> extends Collection<E> {
    ...
}

interface List<E> extends Collection<E> {
    boolean add(int, E);
    E get(int);
    E remove(int);
    E set(int, E);
    ...
}

To iterate over a collection, use a for loop:

```
Collection<E> c = ...;
for(E e : c) {
    ...
}
```
4. Strings and Collections  (15 points)  

(a) 7 points  Suppose we have a method areAnagrams (you wrote such a method in A2): 

/** Return true iff s and t are anagrams of each other. */
public static boolean areAnagrams(String s, String t) { ... } 

Complete method anagramIndices below according to its specification. 

/** Return a sorted list with the indices of Strings in l that are anagrams of s. 
 * Precondition: l != null, s != null. */
public static ArrayList<Integer> anagramIndices(ArrayList<String> l, String s) {

}

(b) 8 points  Complete method getChars below according to its specification. Note that Set is an interface, so you will have to use an implementing class to construct the actual set. 

/** Return a set of Characters in b, but exclude the blank character (space). 
public static Set<Character> getChars(char[] b) {
5. **Recursion** (12 Points)

(a) **6 points** Define the fosterial function \( f(n,k) \) as follows:

- \( f(1,k) = f(0,k) = 1 \)
- If \( n > 1 \) and \( n \) is divisible by \( k \), \( f(n,k) \) is the product of \( f(n-1,k) \), \( f(n-2,k) \), and \( n \).
- If \( n > 1 \) and \( n \) is not divisible by \( k \), \( f(n,k) \) is the product of \( f(n-1,k) \), and \( n \).

Complete function `fosterial` below according to its specification.

```java
/** Return the fosterial value f(n,k).
 * Precondition: n >= 0, k > 0 */
public static int fosterial(int n, int k) {
}
```

(b) **6 points** Complete the following function body. Do not change \( n \) into a String or other char-valued thing. Work only with type int.

```java
/** Return true iff the decimal representation of n has a 5 in it.
 * Example hasFive(515253) is true, hasFive(12346) is false.
 * Precondition: n >= 0. */
public static boolean hasFive(int n) {
}
```
