The exam is closed book and closed notes. Do not begin until instructed.

You have 90 minutes. Good luck!

Write your name and Cornell netid at the top of EACH page! There are 5 questions on 12 numbered pages, front and back. Check that you have all the pages. When you hand in your exam, make sure your booklet is still stapled together. If not, please use our stapler to reattach all your pages!

We have scrap paper available. If you do a lot of crossing out and rewriting, you might want to write code on scrap paper first and then copy it to the exam, so that we can make sense of what you handed in.

Write your answers in the space provided. Ambiguous answers will be considered incorrect. You should be able to fit your answers easily into the space provided.

In some places, we have abbreviated or condensed code to reduce the number of pages that must be printed for the exam. In others, code has been obfuscated to make the problem more difficult. This does not mean that its good style.
### 1. True / False (20 points)

2. **Short Answer** (10 points)

(a) 2 points  If a heap is implemented by storing the elements in a Java array, the left child of the node at index \( k \) will be at what index?

(b) 2 points  If you wanted to write your own exception class, what Java class could you extend?

(c) 3 points  In a binary tree of depth \( d \), what is the maximum and minimum number of nodes it could have?

(d) 3 points  Draw a non-planar graph of minimal size.
3. **Complexity and Induction** (15 points)

(a) **3 points** What is the tightest bound on the time complexity of the following function? Be careful! This requires you to know the complexity of all operations and function calls below.

```java
/** Return the sum of the values in list. */
public static int sumLinkedList(LinkedList<Integer> list) {
    int sum = 0;
    for (int i = 0; i < list.size(); i = i+1){
        sum = sum + list.get(i);
    }
    return sum;
}
```

(b) **4 points** Can the function body in part (a) be rewritten to improve the time complexity—perhaps using a different loop? If so, rewrite it below and state what the best possible time complexity is. If not, explain why no improvement over your answer from part (a) is possible.
(c) 8 points  Let $P(n)$ be: $9^n - 4^n$ is divisible by 5. Prove by induction that $P(n)$ holds for all integers $n \geq 0$.

(i) 2 points Write the base case(s) for your proof.

(ii) 3 points Write the inductive hypothesis for your proof.

(iii) 3 points Complete the inductive step for your proof.
4. **Trees** (25 points)

(a) **3 points**  Given the following pre-order and in-order tree traversals, draw the tree.

<table>
<thead>
<tr>
<th>Pre-order</th>
<th>A, B, C, D, E, F</th>
</tr>
</thead>
<tbody>
<tr>
<td>In-order</td>
<td>B, A, D, E, C, F</td>
</tr>
</tbody>
</table>

(b) **3 points**  Given the following tree, state the post-order tree traversal.

![Tree Diagram]
(c) 19 points  The following questions pertain to class TreeNode defined below:

```java
public class TreeNode {
    public int value;
    public TreeNode left;
    public TreeNode right;
    public int size; // The number of nodes in this tree, including this node
}
```

(i) 7 points Complete method `initSize` according to its specification:

```java
/** Initialize field size in t and in all of its descendants.
 * Return the size of t. */
public static int initSize(TreeNode t) {
```
The inorder traversal of a tree visits the nodes in a certain order. An example is given in the tree below, where the number in each node is the node’s inorder-index. Note that if tree $t$ has 3 nodes in its left subtree, its root is numbered 3. Note: The values of each node may be different from the numbers given below. The tree is not necessarily a Binary Search Tree.

```
/** Return node number $n$ of the inorder traversal of tree $t$.
 * Precondition: $t$ != null && $n$ >= 0 && $n$ < $t$.size
 * and field size is initialized in $t$ and all its descendants. */
public static TreeNode findN(TreeNode $t$, int $n$) {
```

Complete method `findN` according to its specification. There is no need to check the preconditions; assume they are true. You may and should use field `size` from the previous question. **Your solution must run in time $O(h)$ for full credit, where $h$ is the height of the tree.**

```
```
5. **Graphs** (30 points)

(a) 5 points  Consider the following graph:

List the edges of the graph above in the order they would be added to a minimum spanning tree by Prim’s algorithm. If a starting node is required, start with node $a$. An edge should be listed by the pair of vertices it joins. For example, the edge with weight 15 above would be edge $(d, e)$.
(b) 10 points  Consider the following graph:

Execute Dijkstra’s shortest-path algorithm on the graph above with a as the start node. We show the initial state, before iteration 0 of the main loop, in the second column below, giving the frontier set (the blue set in the description of Dijkstra’s algorithm given in lecture), and the $L$ value for each node so far.

For each iteration 0, 1, 2, ..., first write in the appropriate place in the table the Selected node, that is, the node that gets removed from the frontier set. Below that, write the new value of the frontier set and the $L$ values that change on this iteration.

<table>
<thead>
<tr>
<th>Node label</th>
<th>Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected Node</td>
<td>N/A</td>
</tr>
<tr>
<td>Frontier Set</td>
<td>{a}</td>
</tr>
<tr>
<td>$L[a]$</td>
<td>0</td>
</tr>
<tr>
<td>$L[b]$</td>
<td>$\infty$</td>
</tr>
<tr>
<td>$L[c]$</td>
<td>$\infty$</td>
</tr>
<tr>
<td>$L[d]$</td>
<td>$\infty$</td>
</tr>
<tr>
<td>$L[e]$</td>
<td>$\infty$</td>
</tr>
<tr>
<td>Iteration</td>
<td>Init 0 1 2 3 4 Final</td>
</tr>
</tbody>
</table>
(c) **15 points** Consider the following class representing a node in an undirected graph.

```java
public class Node {
    public HashSet<Node> neighbors;
}
```

Let \( n \) be a node of a graph \( g \). The connected component of \( g \) that contains \( n \) is the subgraph containing all nodes (and their edges) that are connected to \( n \) by some path. The graph could consist of a bunch of connected components, none of which are connected to each other.

Complete functions `numComponents` and `dfs` below according to their specifications.

```java
/** Return the number of connected components in graph g. */
public static int numComponents(HashSet<Node> g) {
    HashSet<Node> visited= new HashSet<Node>();
    // Put declarations of local variables and initialization here

    for ( Node n : g) {

    }

    // Put your return statement here
}

/** Precondition: n is not in visited. Add every Node reachable from n along paths of unvisited nodes to visited. */
public static void dfs(Node n, HashSet<Node> visited) {

}
```
Extra Credit (5 points, all or nothing)

Consider a situation where your input int array of size \( n \) is almost sorted.

\[
[1, 4, 3, 2, 5, 7, 6, 8]
\]

In this array, each number is at most \( k \) positions away from its correctly sorted position. In the above example, \( k = 2 \). Complete procedure sort below according to its specification. You may use whatever data structure you would like and may use its methods without implementation as long as your intentions are clear.

Your solution must run in \( O(n \log k) \) time and be clearly organized for credit.

```java
/** Sort the array.
   * Precondition: Each element is no more than \( k \)
   * positions away from where it should be in sorted order */
public void sort(int[] b, int k) {
```
