Important Announcements

- A4 is out now and due two weeks from today. Have fun, and start early!

Tree Overview

- Tree: data structure with nodes, similar to linked list
  - Each node may have zero or more successors (children)
  - Each node has exactly one predecessor (parent) except the root, which has none
  - All nodes are reachable from root

A picture of a singly linked list:

```
2   1   1   0
    |   |
  Node object   pointer
```

- Today: trees!

Binary Trees

- A binary tree is a particularly important kind of tree where every node has at most two children.
  - In a binary tree, the two children are called the left and right children.

Binary trees were in A1!

- You have seen a binary tree in A1.
  - A PhD object has one or two advisors. (Confusingly, my advisors are my “children.”)

**Tree Terminology**

- The root of the tree (no parents)
- Left child of M
- Right child of M
- The leaves of the tree (no children)

- Ancestors of B
- Descendants of W

**Tree Terminology**

- Left subtree of M

A node’s depth is the length of the path to the root. A tree’s (or subtree's) height is the length of the longest path from the root to a leaf.

**Tree Terminology**

- Multiple trees: a forest.

**Class for general tree nodes**

```java
class GTreeNode<T> {
    private T value;
    private List<GTreeNode<T>> children;
    // appropriate constructors, getters, setters, etc.
}
```

Parent contains a list of its children.
Class for general tree nodes

```java
class GTreeNode<T> {
    private T value;
    private List<GTreeNode<T>> children;
    //appropriate constructors, getters, setters, etc.
}
```

Java.util.List is an interface! It defines the methods that all implementation must implement. Whoever writes this class gets to decide what implementation to use — ArrayList? LinkedList? Etc.?

Class for binary tree node

```java
class TreeNode<T> {
    private T value;
    private TreeNode<T> left, right;
    /** Constructor: one-node tree with datum x */
    public TreeNode(T d) { datum= d; left= null; right= null; }
    /** Constr: Tree with root value x, left tree l, right tree r */
    public TreeNode(T d, TreeNode<T> l, TreeNode<T> r) { datum= d; left= l; right= r; }
    //more methods: getValue, setValue, getLeft, setLeft, etc.
}
```

Either might be null if the subtree is empty.

Binary versus general tree

In a binary tree, each node has up to two pointers to the left subtree and to the right subtree:
- One or both could be null, meaning the subtree is empty (remember, a tree is a set of nodes)

In a general tree, a node can have any number of child nodes (and they need not be ordered)
- Very useful in some situations ...
- ... one of which may be in an assignment!

An Application: Syntax Trees

```
(1 + (9 - 2)) * 7
```

A Java expression as a string.

```
1 9 2
```

An expression as a tree.

Applications of Tree: Syntax Trees

- Most languages (natural and computer) have a recursive, hierarchical structure
- This structure is implicit in ordinary textual representation
- Recursive structure can be made explicit by representing sentences in the language as trees: Abstract Syntax Trees (ASTs)
- ASTs are easier to optimize, generate code from, etc. than textual representation
- A parser converts textual representations to AST

We’ll talk more about expressions and trees in next lecture
A Tree is a Recursive Thing

A binary tree is either null or an object consisting of a value, a left binary tree, and a right binary tree.

Looking at trees recursively

A Recipe for Recursive Functions

Base case:
If the input is “easy,” just solve the problem directly.

Recursive case:
Get a smaller part of the input (or several parts).
Call the function on the smaller value(s).
Use the recursive result to build a solution for the full input.
Recursive Functions on Binary Trees

Base case:
- empty tree (null)
- or, possibly, a leaf

Recursive case:
- Call the function on each subtree.
- Use the recursive result to build a solution for the full input.

Searching in a Binary Tree

### Recursive Search

```java
/** Return true iff x is the datum in a node of tree t */
public static boolean treeSearch(T x, TreeNode<T> t) {
    if (t == null) return false;
    if (x.equals(t.datum)) return true;
    return treeSearch(x, t.left) || treeSearch(x, t.right);
}
```

### Example Tree

```
     2
    / \  
   6   7
  /  
 3   4
```

**Very Important!**
- We sometimes talk of `t` as the root of the tree.
- But we also use `t` to denote the whole tree.

Some useful methods – what do they do?

```java
/** Method A */
public static boolean A(Node n) {
    return n != null && n.left == null && n.right == null;
}

/** Method B */
public static int B(Node n) {
    if (n == null) return -1;
    return 1 + Math.max(B(n.left), B(n.right));
}

/** Method C */
public static int C(Node n) {
    if (n == null) return 0;
    return 1 + C(n.left) + C(n.right);
}
```

**Some useful methods**

```java
/** Return true iff node n is a leaf */
public static boolean isLeaf(Node n) {
    return n != null && n.left == null && n.right == null;
}

/** Return height of node n (postorder traversal) */
public static int height(Node n) {
    if (n == null) return -1;  // empty tree
    return 1 + Math.max(height(n.left), height(n.right));
}

/** Return number of nodes in n (postorder traversal) */
public static int numNodes(Node n) {
    if (n == null) return 0;
    return 1 + numNodes(n.left) + numNodes(n.right);
}
```

Binary Search Tree (BST)

A **binary search tree** is a binary tree that is ordered and has no duplicate values. In other words, for every node:
- All nodes in the left subtree have values that are less than the value in that node, and
- All values in the right subtree are greater.

A BST is the key to making search way faster.
**Binary Search Tree (BST)**

Compare binary tree to binary search tree:

```java
boolean searchBST(n, v):
if n==null, return false
if n.v == v, return true
if v < n.v
    return searchBST(n.left, v)
else
    return searchBST(n.right, v)
```

2 recursive calls

```java
boolean searchBT(n, v):
if n==null, return false
if n.v == v, return true
return searchBST(n.left, v) || searchBST(n.right, v)
```

**Building a BST**

- To insert a new item:
  - Pretend to look for the item
  - Put the new node in the place where you fall off the tree

In this example, the BST uses alphabetical order. We inserted the months into the tree in calendar order.

---

**What can go wrong?**

A BST makes searches very fast, unless nodes are inserted in increasing order!

If data arrives in random order, the tree becomes balanced (both subtrees for any node are about the same size).

In this example, we’ve inserted the months in alphabetical order.

---

**Tree traversals**

"Walking" over the whole tree is a tree traversal: Done often enough that there are standard names

Previous example:
- inorder traversal
  - Process left subtree
  - Process root
  - Process right subtree

Note: Can do other processing besides printing

Other standard kinds of traversals
- preorder traversal
  - Process root
  - Process left subtree
  - Process right subtree
- postorder traversal
  - Process left subtree
  - Process right subtree
- level-order traversal
  - Not recursive: uses a queue (we’ll cover this later)

---

**Printing contents of BST**

Because of ordering rules for a BST, it’s easy to print the items in alphabetical order
- Recursively print left subtree
- Print the node
- Recursively print right subtree

**Useful facts about binary trees**

Max # of nodes at depth d: $2^d$

- If height of tree is h
  - min # of nodes: $h + 1$
  - max # of nodes in tree: $2^0 + \ldots + 2^h = 2^{h+1} - 1$

Complete binary tree
- All levels of tree down to a certain depth are completely filled

Things to think about

What if we want to delete data from a BST?

A BST works great as long as it’s balanced.
There are kinds of trees that can automatically keep themselves balanced as you insert things!
