</tbody>
</table>

The exam is closed book and closed notes. Do not begin until instructed.

You have **90 minutes**. Good luck!

Write your name and Cornell NetID, **legibly**, at the top of every page! There are 6 questions on 8 numbered pages, front and back. Check that you have all the pages. When you hand in your exam, make sure your pages are still stapled together. If not, please use our stapler to reattach all your pages!

We have scrap paper available. If you do a lot of crossing out and rewriting, you might want to write code on scrap paper first and then copy it to the exam so that we can make sense of what you handed in.

Write your answers in the space provided. Ambiguous answers will be considered incorrect. You should be able to fit your answers easily into the space provided.

In some places, we have abbreviated or condensed code to reduce the number of pages that must be printed for the exam. In others, code has been obfuscated to make the problem more difficult. This does not mean that it’s good style.

**Academic Integrity Statement:** I pledge that I have neither given nor received any unauthorized aid on this exam. I will not talk about the exam with anyone in this course who has not yet taken Prelim 2.

(�signature)

1. **Name** (1 point)

Write your name and NetID, **legibly**, at the top of every page of this exam.
2. Short Answer  (18 points)

(a) True / False 8 points  Circle T or F in the table below.

<table>
<thead>
<tr>
<th></th>
<th>T</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a)</td>
<td>x.equals(y) returns false, then x.hashCode() != y.hashCode() evaluates to true.</td>
<td>false</td>
</tr>
<tr>
<td>(b)</td>
<td>ArrayList&lt;String&gt; is a subtype of ArrayList&lt;Object&gt;. (Recall that String[] is a subtype of Object[].)</td>
<td>false</td>
</tr>
<tr>
<td>(c)</td>
<td>The expected time complexity to search for a value in a binary tree is O(log n), assuming n is the number of nodes in the tree. There is no ordering of values in a binary tree.</td>
<td>false</td>
</tr>
<tr>
<td>(d)</td>
<td>A connected graph with n nodes has at least n edges.</td>
<td>false</td>
</tr>
<tr>
<td>(e)</td>
<td>A JButton in a GUI must be “listened to” by only one actionPerformed procedure, which defines what happens when the button is clicked.</td>
<td>false</td>
</tr>
<tr>
<td>(f)</td>
<td>Breadth-first search maintains a queue of nodes that have been visited. It maintains a set, not a queue.</td>
<td>false</td>
</tr>
<tr>
<td>(g)</td>
<td>The worst-case time complexity to compute the out-degree of a node is asymptotically slower for the adjacency-list representation of a graph than for the adjacency-matrix representation. For both: in the worst case, a node can have O(n) edges leaving it.</td>
<td>false</td>
</tr>
<tr>
<td>(h)</td>
<td>Quicksort is unstable.</td>
<td>true</td>
</tr>
</tbody>
</table>

(b) 6 points Choose the tightest asymptotic complexity from $O(n^2)$, $O(n)$, $O(n \log n)$, and $O(\log n)$ for the following snippets of code:

1. for (int i = 1; i < n; i = i+1) {
   for (int j = i; j > 1; j = j/2) {
      count++;
   }
}

   Answer: $O(n \log n)$

2. for (int i = 1; i < n; i = i+1) {
   str = str + i; // str is an instance of String
}

   Answer: $O(n^2)$

(c) 4 points Hashing. The array to the right, of size 5, is an implementation of a hash set. The table below shows each element’s hashCode. Answer questions (1) and (2) below. Each is independent of the other. Do not be concerned with resizing the array.

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>hashset</td>
<td>a</td>
<td>c</td>
<td>b</td>
<td></td>
<td></td>
</tr>
<tr>
<td>element</td>
<td>a</td>
<td>b</td>
<td>c</td>
<td>d</td>
<td></td>
</tr>
<tr>
<td>hashCode</td>
<td>0</td>
<td>9</td>
<td>16</td>
<td>14</td>
<td></td>
</tr>
</tbody>
</table>

(1) 2 points. List the bucket indexes that linear probing will probe if d is inserted into the hash set. 4, 0, 1, 2

(2) 2 points. List the bucket indexes that quadratic probing will probe if d is inserted into the hash set. 4, 0, 3
3. **Heaps** (10 Points)

This question explores parts of algorithm heapsort, which sorts array c shown to the right. We use the identifier m for the expression c.length, and you can too.

In these programming problems, you may write `swap x and y` instead of the real Java statements to swap the two variables.

(a) 5 points Assume that 0 ≤ j < m and that c[0..j-1] is a max-heap, as shown to the right. State in one (short) sentence what has to be done to make c[0..j] into a heap. Details are not wanted; just state what has to be done.

Bubble c[j] up to the appropriate position in the heap.

(b) 5 points Write the body of method `sortHeap`, given below. It will use a loop, and its loop invariant is shown to the right. You may assume the existence of the following function:

```java
/** Bubble c[0] down to its appropriate position in c[0..j-1].
 * Precondition: c[0..j-1] is a max-heap except that c[0] may be out of place. */
public static void bubbleDown(int[] c, int j) { }

/** Sort c. Precondition: c is a max-heap. */
public static void sortHeap(int[] c) {
    int j = m;
    while (j > 0) {
        j = j - 1;
        Swap c[0] and c[j];
        bubbleDown(c, j);
    }
}
```

Note that it says that c[0..j-1] <= c[j..m-1]
4. Trees (25 Points)

(a) 4 points
Write down the inorder traversal sequence and postorder traversal sequence for the tree to the right.

inorder: a e c f b d.
postorder: e f c d b a

(b) 8 points
Class TNode, to the right, is used in building binary trees. Complete recursive function areDifferent below. (Trees p and q are the different if they have different structure or if the value of any node is different.)

```java
public class TNode {
    String val; // value stored in the node
    TNode left; // left subtree (null if empty)
    TNode right; // right subtree (null if empty)
}

/** Return true if trees p and q are different trees. 
   Note: p == null or q == null denotes an empty tree. **/
public boolean areDifferent(TNode p, TNode q) {
    if (p == null && q == null) return false;
    if (p == null || q == null) return true;
    if (!p.val.equals(q.val)) return true;
    return areDifferent(p.left, q.left) || areDifferent(p.right, q.right);
}
```

What is the tightest worst-case time complexity of this function in terms of \(np\) and \(nq\), the number of nodes in trees p and q? Circle one of these possibilities:

\[ O(np) \quad O(nq) \quad O(np + nq) \quad O(\max(np, nq)) \quad O(\min(np, nq)) \quad O(\min(np, nq)) \]
(c) 10 points  Complete the recursive function isBST, below.

```java
/** Return true iff t is a binary search tree in which all values are greater
 * than s1 and less than s2 using lexicographic ordering --- all values are
 * strictly between s1 and s2.
 * Note: String implements Comparable. You may use String method compareTo. */
 * Note: t=null denotes the empty tree. */
public static boolean isBST(TNode t, String s1, String s2) {
    if (t == null) return true;
    if (t.val.compareTo(s1) <= 0 || t.val.compareTo(s2) >= 0) return false;
    return isBST(t.left, h, t.val) && isBST(t.right, t.val, k);
}
```

(d) 3 points  Draw the BST by starting with an empty BST and inserting these values, one by one, into it: [j, a, b, x, u, v]. Use the conventional dictionary ordering of characters.

```
j
 / 
 a  x
 / 
 b  u
    
 v
```
5. Collections and Interface (10 Points)

Answer these questions based on the part of Java collections framework shown in the diagram below. In this picture, *italic font* indicates an Interface, and *bold font* indicates a non-abstract class.

![Java Collections Framework Diagram]

(a) 2 points Does the following statement compile? If not, explain why.
```
Set<Integer> s = new Set<>();
```

It does not compile. An interface cannot be instantiated.

(b) 3 points Let h have type `HashSet<E>` and ll have `LinkedList<E>`. What are the worst-case time complexities of `h.add(e)`, `ll.add(e)`, and `ll.add(k, e)` for some object `e`, assuming there are `n` elements in the set or list? $O(n)$, $O(1)$, $O(k)$.

(c) 5 points Class `HashSet<E>` contains the following method:

```java
/** Add e to this set if it is not in the set.
   * Return true iff e was added. */
public boolean add(E e) { ... }
```

Assume method `contains` is not in class `HashSet<E>`. Implement the following function using function `add`. It should take expected time $O(1)$. You can use other HashSet methods, but no loops.

```java
/** Return true iff s contains x */
public static boolean contains(HashSet<String> s, String x) {
    boolean b = s.add(x);
    if (b) {s.remove(x); return false; }
    return true;
}
```
6. Sorting (12 Points)

(a) 4 points For each of the following sorting algorithms, fill in their tightest expected space and time complexity in terms of big O. For Quick Sort, assume it is the version that reduces the space as much as possible.

<table>
<thead>
<tr>
<th></th>
<th>Quick Sort</th>
<th>Merge Sort</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expected Space Complexity</td>
<td>$O(\log n)$</td>
<td>$O(n)$</td>
</tr>
<tr>
<td>Expected Time Complexity</td>
<td>$O(n \log n)$</td>
<td>$O(n \log n)$</td>
</tr>
</tbody>
</table>

(b) 8 points To the left is a framework of mergeSort. On the right are the precondition and postcondition of method merge.

```java
/** Sort b[h..k-1] */
public void mergesort(int[] b, int h, int k) {
    if (k - h <= 2) return;
    int t = (h + k) / 2;
    mergeSort(b, h, t);
    mergeSort(b, t, k-1);
    merge(b, h, t, k-1);
}
```

(1) 4 points. Above, the recursive calls to mergeSort have missing arguments, denoted by `par1`, `par2`, `par3`, `par4`. Write what they should be according to the pre- and post-condition of merge.

```
par1 | par2 | par3 | par4
-----|------|------|------
h    | t    | t    | k
```

(2) 2 points. There is an error in the above code. Explain what is wrong and give the corrected version. The expression $k - h <= 2$ should be $k - h < 2$.

(3) 2 points. The statement `int t = (k + h) / 2;` would be better written as `int t = h + (k - h) / 2;`. Explain the reason in one sentence. $k + h$ may be bigger than `Integer.MAX_VALUE`, causing wraparound and a mistake.
7. Graphs (20 Points)

(a) 8 points Answer questions based on the graph to the right.

(1) 2 points Show the topological sorting sequence for the graph.
    a b e c d.

(2) 4 points Complete the adjacency list for the graph, in the format shown for node c, which we provided. The order of nodes in a list does not matter,

```
    a -> b -> e -> null
    b -> c -> d -> e -> null
    c -> d -> null
    d -> null
    e -> c -> null
```

(3) 2 points What is the minimal number of edges you can add to this graph to make it nonplanar? 3.

To be nonplanar, it needs a copy of K5 or K3,3. Since there are only 5 nodes, it can’t have a copy of K3,3, which has 6 nodes. To make this graph K5, you need to add 3 edges.

(b) 4 points State the theorem that is proved about the invariant in our development of Dijkstra’s shortest path algorithm. Let node f have minimum d-value (distance value) among nodes in the frontier set. Then that d-value is f’s shortest-path distance.

(c) 4 points Here is one algorithm for constructing a spanning tree of a connected graph with n nodes and e edges: Start with all the nodes of the graph but no edges. Repeat until no longer possible: Add any edge of the graph that does not introduce a cycle. How many edges will this algorithm add? A spanning tree has n − 1 edges, so n − 1 nodes will be added.

(d) 4 points Complete the following method. Make it recursive. You can write “visit n” without explaining how to visit a node and “n is visited” or “n is unvisited” to check whether a node has been visited. You can also use an English phrase to get all the neighbors of a given node.

```java
/** Visit all nodes reachable along unvisited paths from node v. */
/** Precondition: v has not been visited. */
public void visitNodes(Node v) {
    visit v;
    for each neighbor w of v {
        if (w has not been visited) visitNodes(w);
    }
}
```
