Syscalls, exceptions, and interrupts, ...oh my!

Anne Bracy
CS 3410
Computer Science
Cornell University

The slides were originally created by Deniz ALTINBUKEN.

P&H Chapter 4.9, pages 445–452, appendix A.7
Operating System

- Manages all of the software and hardware on the computer
- Many processes running at the same time, requiring resources
  - CPU, Memory, Storage, etc.

- The Operating System *multiplexes* these resources amongst different processes, and *isolates* and *protects* processes from one another!
Operating System

- Operating System (OS) is a trusted mediator:
  - Safe control transfer between processes
  - Isolation (memory, registers) of processes
One Brain, Many Personalities

You are what you execute.

Personalities:
- hailstone_recursive
- Microsoft Word
- Minecraft

Linux ← yes, this is just software like every other program that runs on the CPU

Are they all equal?
Trusted vs. Untrusted

• Only **trusted** processes should access & change important things
  • Editing TLB, Page Tables, OS code, OS $sp, OS $fp...

• If an **untrusted** process could change the OS’ $sp/$fp/$gp/etc., OS would crash!
Privileged Mode

CPU Mode Bit in Process Status Register

• Many bits about the current process
• Mode bit is just one of them

• Mode bit:
  • 0 = user mode = untrusted: “Privileged” instructions and registers are disabled by CPU
  • 1 = kernel mode = trusted
All instructions and registers are enabled
Privileged Mode at Startup

1. Boot sequence
   - load first sector of disk (containing OS code) to predetermined address in memory
   - Mode $\leftarrow 1$; PC $\leftarrow$ predetermined address

2. OS takes over
   - initializes devices, MMU, timers, etc.
   - loads programs from disk, sets up page tables, etc.
   - Mode $\leftarrow 0$; PC $\leftarrow$ program entry point
     - User programs regularly yield control back to OS
Users need access to resources

If an untrusted process does not have privileges to use system resources, how can it

- Use the screen to print?
- Send message on the network?
- Allocate pages?
- Schedule processes?

Solution: System Calls
System Call Examples

**putc()**: Print character to screen
  - Need to multiplex screen between competing processes

**send()**: Send a packet on the network
  - Need to manipulate the internals of a device

**sbrk()**: Allocate a page
  - Needs to update page tables & MMU

**sleep()**: put current prog to sleep, wake other
  - Need to update page table base register
System Calls

System call: **Not** just a function call

- Don’t let process jump just anywhere in OS code
- OS can’t trust process’ registers (sp, fp, gp, etc.)

**SYSCALL instruction**: safe control transfer to OS

MIPS system call convention:

- Exception handler saves temp regs, saves ra, ...
- $v0 = system call number, which specifies the operation the application is requesting
Libraries and Wrappers

Compilers do not emit SYSCALL instructions
  • Compiler doesn’t know OS interface

Libraries implement standard API from system API libc (standard C library):
  • `gets()` → `getc()`
  • `getc()` → `syscall`
  • `sbrk()` → `syscall`
  • `printf()` → `write()`
  • `write()` → `syscall`
  • `malloc()` → `sbrk()`
  • ...

Invoking System Calls

char *gets(char *buf) {
    while (...) {
        buf[i] = getc();
    }
}

int getc() {
    asm("addiu $v0, $0, 4");
    asm("syscall");
}

??
gets
getc
Where does the OS live?

In its own address space?

- Syscall has to switch to a different address space
- Hard to support syscall arguments passed as pointers
  . . . So, NOPE

In the same address space as the user process?

- Protection bits prevent user code from writing kernel
- Higher part of virtual memory
- Lower part of physical memory
  . . . Yes, *this is how we do it*. 
All kernel text & most data:
• At same virtual address in every address space

OS is omnipresent, available to help user-level applications
• Typically in high memory

Which statement is FALSE?

A) OS manages the CPU, Memory, Devices, and Storage.
B) OS provides a consistent API to be used by other processes.
C) The OS kernel is always present on Disk.
D) The OS kernel is always present in Memory.
E) Any process can fetch and execute OS code in user mode.
Inside the SYSCALL instruction

SYSCALL instruction does an atomic jump to a controlled location (i.e. MIPS 0x8000 0180)

- Switches the sp to the kernel stack
- Saves the old (user) SP value
- Saves the old (user) PC value (= return address)
- Saves the old privilege mode
- Sets the new privilege mode to 1
- Sets the new PC to the kernel syscall handler
Inside the SYSCALL implementation

Kernel system call handler carries out the desired system call

- Saves callee-save registers
- Examines the syscall number
- Checks arguments for sanity
- Performs operation
- Stores result in v0
- Restores callee-save registers
- Performs a “return from syscall” (ERET) instruction, which restores the privilege mode, SP and PC
Anything that *isn’t* a user program executing its own user-level instructions.

**System Calls:**

- just one type of exceptional control flow
- Process requesting a service from the OS
- Intentional – *it’s in the executable!*
Software Exceptions

**Trap**
*Intentional*
Examples:
*System call*
*(OS performs service)*
*Breakpoint traps*
*Privileged instructions*

**Fault**
*Unintentional but Possibly recoverable*
Examples:
*Division by zero*
*Page fault*

**Abort**
*Unintentional Not recoverable*
Examples:
*Parity error*

*One of many ontology / terminology trees.*
Hardware support for exceptions

Exception program counter (EPC)
- 32-bit register, holds addr of affected instruction
- Syscall case: Address of SYSCALL

Cause register
- Register to hold the cause of the exception
- Syscall case: 8, Sys

Special instructions to load TLB
- Only do-able by kernel
Precise Exceptions

Hardware guarantees

• Previous instructions complete
• Later instructions are flushed
• EPC and cause register are set
• Jump to prearranged address in OS
• When you come back, restart instruction

• Disable exceptions while responding to one
  – Otherwise can overwrite EPC and cause
Hardware interrupts
- Asynchronous
  - caused by events external to CPU

Software exceptions
- Synchronous
  - caused by CPU executing an instruction

Maskable
- Can be turned off by CPU
  - Example: alert from network device that a packet just arrived, clock notifying CPU of clock tick

Unmaskable
- Cannot be ignored
  - Example: alert from the power supply that electricity is about to go out
No **SYSCALL** instruction. **Hardware** steps in:

- Saves PC of exception instruction (EPC)
- Saves cause of the interrupt/privilege (Cause register)
- Switches the sp to the kernel stack
- Saves the old (user) SP value
- Saves the old (user) PC value
- Saves the old privilege mode
- Sets the new privilege mode to 1
- Sets the new PC to the kernel **syscall** handler

interrupt/exception handler
Inside Interrupts & Unanticipated Exceptions

Interrupt/exception handler handles event

Kernel system call handler carries out system call all

- Saves callee-save registers
- Examines the syscall number cause
- Checks arguments for sanity
- Performs operation
- Stores result in v0 all
- Restores callee-save registers
- Performs a ERET instruction (restores the privilege mode, SP and PC)
Clicker Question

What other task requires both Hardware and Software?

A) Virtual to Physical Address Translation
B) Branching and Jumping
C) Clearing the contents of a register
D) Pipelining instructions in the CPU
E) What are we even talking about?
Virtual → physical address translation!

**Hardware**
- has a concept of operating in physical or virtual mode
- helps manage the TLB
- raises page faults
- keeps Page Table Base Register (PTBR) and ProcessID

**Software/OS**
- manages Page Table storage
- handles Page Faults
- updates Dirty and Reference bits in the Page Tables
- keeps TLB valid on context switch:
  - Flush TLB when new process runs (x86)
  - Store process id (MIPS)
 Demand Paging on MIPS

1. TLB miss
2. Trap to kernel
3. Walk Page Table
4. Find page is invalid
5. Convert virtual address to file + offset
6. Allocate page frame
   - Evict page if needed
7. Initiate disk block read into page frame
8. Disk interrupt when DMA complete
9. Mark page as valid
10. Load TLB entry
11. Resume process at faulting instruction
12. Execute instruction
