Parallelism, Multicore, and Synchronization

Hakim Weatherspoon
CS 3410
Computer Science
Cornell University

[Weatherspoon, Bala, Bracy, McKee, and Sirer, Roth, Martin]
IT TOOK A LOT OF WORK, BUT THIS LATEST LINUX PATCH ENABLES SUPPORT FOR MACHINES WITH 4,096 CPUs, UP FROM THE OLD LIMIT OF 1,024.

DO YOU HAVE SUPPORT FOR SMOOTH FULL-SCREEN FLASH VIDEO YET?

NO, BUT WHO USES THAT?
Big Picture: Multicore and Parallelism

Why do I need four computing cores on my phone?!
Big Picture: Multicore and Parallelism

Why do I need eight computing cores on my phone?!
Big Picture: Multicore and Parallelism

Why do I need sixteen computing cores on my phone?!
Pitfall: Amdahl’s Law

Execution time after improvement =
\[
\text{affected execution time} \div \text{amount of improvement} + \text{execution time unaffected}
\]

\[
T_{\text{improved}} = \frac{T_{\text{affected}}}{\text{improvement factor}} + T_{\text{unaffected}}
\]
Pitfall: Amdahl’s Law

Improving an aspect of a computer and expecting a proportional improvement in overall performance

\[ T_{\text{improved}} = \frac{T_{\text{affected}}}{\text{improvement factor}} + T_{\text{unaffected}} \]

Example: multiply accounts for 80s out of 100s

- Multiply can be parallelized
- How much improvement do we need in the multiply performance to get 5× overall improvement?
  
  (a) 2x  (b) 10x (c) 100x (d) 1000x (e) not possible
Pitfall: Amdahl’s Law
Improving an aspect of a computer and expecting a proportional improvement in overall performance

$$T_{\text{improved}} = \frac{T_{\text{affected}}}{\text{improvement factor}} + T_{\text{unaffected}}$$

Example: multiply accounts for 80s out of 100s

• Multiply can be parallelized

• How much improvement do we need in the multiply performance to get 5× overall improvement?

$$20 = \frac{80}{n} + 20 \quad – \text{Can’t be done!}$$
Scaling Example

Workload: sum of 10 scalars, and $10 \times 10$ matrix sum
  • Speed up from 10 to 100 processors?

Single processor: $\text{Time} = (10 + 100) \times t_{\text{add}}$

10 processors
  • $\text{Time} = 100/10 \times t_{\text{add}} + 10 \times t_{\text{add}} = 20 \times t_{\text{add}}$
  • $\text{Speedup} = 110/20 = 5.5$

100 processors
  • $\text{Time} = 100/100 \times t_{\text{add}} + 10 \times t_{\text{add}} = 11 \times t_{\text{add}}$
  • $\text{Speedup} = 110/11 = 10$

Assumes load can be balanced across processors
Takeaway

Unfortunately, we cannot obtain unlimited scaling (speedup) by adding unlimited parallel resources, eventual performance is dominated by a component needing to be executed sequentially. Amdahl's Law is a caution about this diminishing return.
Performance Improvement 101

\[
\frac{\text{seconds}}{\text{program}} = \frac{\text{instructions}}{\text{program}} \times \frac{\text{cycles}}{\text{instruction}} \times \frac{\text{seconds}}{\text{cycle}}
\]

2 Classic Goals of Architects:

\(\downarrow\) Clock period \(\uparrow\) Clock frequency

\(\downarrow\) Cycles per Instruction \(\uparrow\) IPC
Clock frequencies have stalled

**Darling** of performance improvement for decades

Why is this no longer the strategy?

**Hitting Limits:**

- Pipeline depth
- Clock frequency
- Moore’s Law & Technology Scaling
- Power
Exploiting Intra-instruction parallelism:
  Pipelining (decode A while fetching B)

Exploiting Instruction Level Parallelism (ILP):
  Multiple issue pipeline (2-wide, 4-wide, etc.)
  • Statically detected by compiler (VLIW)
  • Dynamically detected by HW

Dynamically Scheduled (OoO)
Instruction-Level Parallelism (ILP)

Pipelining: execute multiple instructions in parallel

Q: How to get more instruction level parallelism?
A: Deeper pipeline

- E.g. 250MHz 1-stage; 500Mhz 2-stage; 1GHz 4-stage; 4GHz 16-stage

Pipeline depth limited by...

- max clock speed (less work per stage ⇒ shorter clock cycle)
- min unit of work
- dependencies, hazards / forwarding logic
Instruction-Level Parallelism (ILP)

Pipelining: execute multiple instructions in parallel

Q: How to get more instruction level parallelism?
A: Multiple issue pipeline

- Start multiple instructions per clock cycle in duplicate stages

ALU/Br

LW/SW
Static Multiple Issue

a.k.a. **Very Long Instruction Word (VLIW)**

Compiler groups instructions to be issued together:
- Packages them into “issue slots”

How does HW detect and resolve hazards?
It doesn’t. 😊 Compiler must avoid hazards

Example: Static Dual-Issue 32-bit RISC-V
- Instructions come in pairs (64-bit aligned)
  - One ALU/branch instruction (or nop)
  - One load/store instruction (or nop)
## RISC-V with Static Dual Issue

### Two-issue packets
- One ALU/branch instruction
- One load/store instruction
- 64-bit aligned
  - ALU/branch, then load/store
  - Pad an unused instruction with nop

Scheduling Example

Schedule this for dual-issue RISC-V

Loop:
lw  t0, s1, 0  # $t0=array element
add  t0, t0, s2  # add scalar in $s2
sw  t0, s1, 0  # store result
addi  s1, s1,–4  # decrement pointer
bne  s1, zero, Loop  # branch $s1!=0

Clicker Question: What is the IPC of this machine?
(A) 0.8  (B) 1.0  (C) 1.25  (D) 1.5  (E) 2.0
Scheduling Example

Schedule this for dual-issue RISC-V

Loop:  
lw $t0, s1, 0  # $t0= array element
add $t0, $t0, s2  # add scalar in $s2
sw $t0, s1, 0    # store result
addi s1, s1,–4   # decrement pointer
bne s1, zero, Loop # branch $s1! = 0

\[
\frac{5 \text{ instructions}}{4 \text{ cycles}} = \text{IPC} = 1.25
\]

\[
\frac{4 \text{ cycles}}{4 \text{ cycles}} = \text{CPI} = 0.8
\]
Techniques and Limits of Static Scheduling

Goal: larger instruction windows (to play with)
• Predication
• Loop unrolling
• Function in-lining
• Basic block modifications (superblocks, etc.)

Roadblocks
• Memory dependences (aliasing)
• Control dependences
Speculation

Reorder instructions

• To fill the issue slot with useful work
• Complicated: exceptions may occur
Optimizations to make it work

Move instructions to fill in nops
   Need to track hazards and dependencies

Loop unrolling
Scheduling Example

Compiler scheduling for dual-issue RISC-V...

Loop:  
lw  t0, s1, 0  # t0 = A[i]
lw  t1, s1, 4  # t1 = A[i+1]
add  t0, t0, s2  # add s2
add  t1, t1, s2  # add s2
sw  t0, s1, -8  # store A[i]
sw  t1, s1, -4  # store A[i+1]
addi  s1, s1, +8  # increment pointer
bne  s1, s3, Loop  # continue if s1!=end

ALU/branch slot
Loop:  
nop
nop
add  t0, t0, s2
add  t1, t1, s2
addi  s1, s1, +8
bne  s1, s3, Loop

lw  t1, s1, 4  2
nop  3
sw  t0, s1, 0  4
sw  t1, s1, 4  5
nop  6

8 cycles
6 cycles

6 cycles
8 instructions = CPI = 0.75
Scheduling Example

Compiler scheduling for dual-issue RISC-V...

Loop:

1. lw t0, s1, 0  # t0 = A[i]
2. lw t1, s1, 4  # t1 = A[i+1]
3. add t0, t0, s2  # add s2
4. add t1, t1, s2  # add s2
5. sw t0, s1, -8  # store A[i]
6. sw t1, s1, -4  # store A[i+1]

addi s1, s1, +8  # increment pointer
bne s1, s3, Loop  # continue if s1!=end

ALU/branch slot
Loop: nop
1. addi s1, s1, +8
2. add t0, t0, s2
3. add t1, t1, s2
4. bne s1, s3, Loop

Load/store slot
1. lw t0, s1, 0  # t0 = A[i]
2. lw t1, s1, 4  # t1 = A[i+1]
3. nop
4. sw t0, s1, -8  # store A[i]
5. sw t1, s1, -4  # store A[i+1]

5 cycles
8 cycles

\[
\frac{5 \text{ cycles}}{8 \text{ instructions}} = \text{CPI} = 0.625
\]
Limits of Static Scheduling

Compiler scheduling for dual-issue RISC-V…

lw  t0, s1, 0  # load A
addi t0, t0, +1 # increment A

Problem: What if $s1 and $s2 are equal (aliasing)? Won’t work
Improving IPC via ILP

Exploiting Intra-instruction parallelism:
• Pipelining (decode A while fetching B)

Exploiting Instruction Level Parallelism (ILP):
Multiple issue pipeline (2-wide, 4-wide, etc.)
• Statically detected by compiler (VLIW)
• Dynamically detected by HW
Dynamically Scheduled (OoO)
Dynamic Multiple Issue

aka **SuperScalar Processor** (c.f. Intel)

- CPU chooses multiple instructions to issue each cycle
- Compiler can help, by reordering instructions….
- … but CPU resolves hazards

Even better: **Speculation/Out-of-order Execution**

- Execute instructions as early as possible
- Aggressive register renaming (indirection to the rescue!)
- Guess results of branches, loads, etc.
- Roll back if guesses were wrong
- Don’t commit results until all previous instructions committed

Effectiveness of OoO Superscalar

It was awesome, but then it stopped improving

Limiting factors?

• Programs dependencies
• Memory dependence detection → be conservative
  - e.g. Pointer Aliasing: A[0] += 1; B[0] *= 2;
• Hard to expose parallelism
  - Still limited by the fetch stream of the static program
• Structural limits
  - Memory delays and limited bandwidth
• Hard to keep pipelines full, especially with branches
**Power Efficiency**

**Q:** Does multiple issue / ILP cost much?

**A:** Yes.

→ Dynamic issue and speculation requires power

- Dual-core Itanium 2
- Itanium 2
- K8
- K10
- Atom

Curve shows 'Moore's Law': transistor count doubling every two years.
Why Multicore?

Moore’s law

- A law about transistors
- Smaller means more transistors per die
- And smaller means faster too

But: Power consumption growing too…
Power Wall

Power = capacitance \times \text{voltage}^2 \times \text{frequency}

In practice: Power \sim \text{voltage}^3

Reducing voltage helps (a lot)
... so does reducing clock speed
Better cooling helps

The power wall

- We can’t reduce voltage further
- We can’t remove more heat
Why Multicore?

**Performance**: 1.2x

**Power**: 1.7x

**Single-Core**

**Performance**: 1.0x

**Power**: 1.0x

Those simpler cores did something very right.
Inside the Processor

AMD Barcelona Quad-Core: 4 processor cores
Inside the Processor

Intel Nehalem Hex-Core

4-wide pipeline
Exploiting Thread-Level parallelism

Hardware multithreading to improve utilization:

• Multiplexing multiple threads on single CPU
• Sacrifices latency for throughput
• Single thread cannot fully utilize CPU? Try more!
• Three types:
  • Course-grain (has preferred thread)
  • Fine-grain (round robin between threads)
  • Simultaneous (hyperthreading)
What is a thread?

Process: multiple threads, code, data and OS state
Threads: share code, data, files, **not** regs or stack

![Diagram showing single-threaded and multi-threaded processes](image)

<td>N</td>
<td>N</td>
</tr>
</tbody>
</table>

Hyperthreads

- HT = Multilssue + extra PCs and registers – dependency logic
- HT = MultiCore – redundant functional units + hazard avoidance

Hyperthreads (Intel)

- Illusion of multiple cores on a single core
- Easy to keep HT pipelines full + share functional units
Example: All of the above

8 die (aka 8 sockets)
4 core per socket
2 HT per core

Note: a socket is a processor, where each processor may have multiple processing cores, so this is an example of a multiprocessor multicore hyperthreaded system
Parallel Programming

Q: So let's just all use multicore from now on!
A: Software must be written as parallel program

Multicore difficulties

- Partitioning work
- Coordination & synchronization
- Communications overhead
- How do you write parallel programs?
  ... without knowing exact underlying architecture?
Work Partitioning

Partition work so all cores have something to do
Load Balancing

Need to partition so all cores are actually working
Amdahl’s Law

If tasks have a **serial part** and a **parallel part**…

**Example:**

step 1: divide input data into $n$ pieces
step 2: do work on each piece
step 3: combine all results

**Recall:** *Amdahl’s Law*

As number of cores increases …

- time to execute parallel part? **goes to zero**
- time to execute serial part? **Remains the same**
- **Serial part eventually dominates**
Amdahl’s Law
Parallelism is a necessity

Necessity, not luxury
  Power wall

Not easy to get performance out of

Many solutions
  Pipelining
  Multi-issue
  Hyperthreading
  Multicore
Parallel Programming

Q: So lets just all use multicore from now on!
A: Software must be written as parallel program

Multicore difficulties

• Partitioning work
• Coordination & synchronization
• Communications overhead
• How do you write parallel programs?
  ... without knowing exact underlying architecture?
Big Picture: Parallelism and Synchronization

How do I take advantage of *parallelism*?
How do I write *(correct)* parallel programs?

What primitives do I need to implement correct parallel programs?
Parallelism & Synchronization

Cache Coherency

- Processors cache shared data → they see different (incoherent) values for the same memory location

Synchronizing parallel programs

- Atomic Instructions
- HW support for synchronization

How to write parallel programs

- Threads and processes
- Critical sections, race conditions, and mutexes
Parallelism and Synchronization

**Cache Coherency Problem:** What happens when two or more processors cache *shared* data?
Parallelism and Synchronization

**Cache Coherency Problem**: What happens when two or more processors cache *shared* data?

i.e. the view of memory held by two different processors is through their individual caches.

As a result, processors can see different *(incoherent)* values to the *same* memory location.
Parallelism and Synchronization
Parallelism and Synchronization

Each processor core has its own L1 cache
Parallelism and Synchronization

Each processor core has its own L1 cache
Parallelism and Synchronization

Each processor core has its own L1 cache
Shared Memory Multiprocessors

Shared Memory Multiprocessor (SMP)
- Typical (today): 2 – 4 processor dies, 2 – 8 cores each
- HW provides *single physical address* space for all processors

![Diagram of Shared Memory Multiprocessor](image)

e) Couldn’t be any of the above

Clicker Question
Cache Coherency Problem, WB $\$$

Thread A (on Core0)
for(int i = 0, i < 5; i++) {
  t0=0  LW t0, addr(x)
  t0=1  ADDIU t0, t0, 1
  x=1   SW t0, addr(x)
}

Thread B (on Core1)
for(int j = 0; j < 5; j++) {
  t0=0  LW t0, addr(x)
  t0=1  ADDIU t0, t0, 1
  x=1   SW t0, addr(x)

Problem! }

![Diagram showing cache coherency problem]
Not just a problem for Write-Back Caches

Executing on a write-thru cache

<table>

</tbody>
</table>
Two issues

Coherence
• What values can be returned by a read
• Need a globally uniform (consistent) view of a single memory location
Solution: Cache Coherence Protocols

Consistency
• When a written value will be returned by a read
• Need a globally uniform (consistent) view of all memory locations relative to each other
Solution: Memory Consistency Models
Coherence Defined

Informal: Reads return most recently written value

Formal: For concurrent processes \( P_1 \) and \( P_2 \)

- \( P \) writes \( X \) before \( P \) reads \( X \) (with no intervening writes)
  \[ \Rightarrow \] read returns written value
  - (preserve program order)

- \( P_1 \) writes \( X \) before \( P_2 \) reads \( X \)
  \[ \Rightarrow \] read returns written value
  - (coherent memory view, can’t read old value forever)

- \( P_1 \) writes \( X \) and \( P_2 \) writes \( X \)
  \[ \Rightarrow \] all processors see writes in the same order
  - all see the same final value for \( X \)
  - Aka write serialization

- (else \( P_A \) can see \( P_2 \)’s write before \( P_1 \)’s and \( P_B \) can see the opposite; their final understanding of state is wrong)
Cache Coherence Protocols

Operations performed by caches in multiprocessors to ensure coherence

- **Migration** of data to local caches
  - Reduces bandwidth for shared memory
- **Replication** of read-shared data
  - Reduces contention for access

**Snooping protocols**

- Each cache monitors bus reads/writes
Snooping for Hardware Cache Coherence

- All caches monitor bus and all other caches
- **Bus read**: respond if you have dirty data
- **Bus write**: update/invalidate your copy of data
Invalidating Snooping Protocols

Cache gets **exclusive access** to a block when it is to be written

- Broadcasts an invalidate message on the bus
- Subsequent read in another cache misses
  - Owning cache supplies updated value

<table>
<thead>
<tr>
<th>Time Step</th>
<th>CPU activity</th>
<th>Bus activity</th>

</tbody>
</table>
Writing

Write-back policies for bandwidth
Write-invalidate coherence policy
• First invalidate all other copies of data
• Then write it in cache line
• Anybody else can read it
Permits one writer, multiple readers

In reality: many coherence protocols
• Snooping doesn’t scale
• Directory-based protocols
  - Caches and memory record sharing status of blocks in a directory
Hardware Cache Coherence

Coherence
- all copies have same data at all times

Coherence controller:
- Examines bus traffic (addresses and data)
- Executes coherence protocol
  - What to do with local copy when you see different things happening on bus

Three processor-initiated events
- **Ld**: load
- **St**: store
- **WB**: write-back

Two remote-initiated events
- **LdMiss**: read miss from another processor
- **StMiss**: write miss from another processor
VI Coherence Protocol

VI (valid-invalid) protocol:

- Two states (per block in cache)
  - V (valid): have block
  - I (invalid): don’t have block
- Can implement with valid bit

Protocol diagram (left)

- If *you* load/store a block: transition to V
- If anyone *else* wants to read/write block:
  - Give it up: transition to I state
  - Write-back if your own copy is dirty
**VI Protocol (Write-Back Cache)**

**Thread A**
- `lw t0, r3, 0`
- `ADDIU t0, t0, 1`
- `sw t0, r3, 0`

**Thread B**
- `lw t0, r3, 0`
- `ADDIU t0, t0, 1`
- `sw t0, r3, 0`

**CPU0**
- `lw t0, r3, 0`
- `ADDIU t0, t0, 1`
- `sw t0, r3, 0`

**CPU1**
- `lw t0, r3, 0`
- `ADDIU t0, t0, 1`
- `sw t0, r3, 0`

**Mem**
- `lw t0, r3, 0`
- `ADDIU t0, t0, 1`
- `sw t0, r3, 0`

**lw** by Thread B generates an “other load miss” event (LdMiss)
  - Thread A responds by sending its dirty copy, transitioning to **I**
Clicker Question:
Core A loads x into a register
Core B wants to load x into a register
What happens?

(A) they can both have a copy of X in their cache
(B) A keeps the copy
(C) B steals the copy from A, and this is an efficient thing to do
(D) B steals the copy from A, and this is a sad shame
(E) B waits until A kicks X out of its cache, then it can complete the load
VI protocol is inefficient

- Only one cached copy allowed in entire system
- Multiple copies can’t exist even if read-only
  - Not a problem in example
  - Big problem in reality

**MSI (modified-shared-invalid)**

- Fixes problem: splits “V” state into two states
  - **M (modified)**: local dirty copy
  - **S (shared)**: local clean copy
- Allows either
  - Multiple read-only copies (S-state) **--OR--**
  - Single read/write copy (M-state)
MSI Protocol (Write-Back Cache)

Thread A

lw t0, r3, 0
ADDIU t0, t0, 1
sw t0, r3, 0

Thread B

lw t0, r3, 0
ADDIU t0, t0, 1
sw t0, r3, 0

lw by Thread B generates a “other load miss” event (LdMiss)
- Thread A responds by sending its dirty copy, transitioning to $S$

sw by Thread B generates a “other store miss” event (StMiss)
- Thread A responds by transitioning to $I$
Coherence introduces two new kinds of cache misses

- **Upgrade miss**
  - On stores to read-only blocks
  - Delay to acquire write permission to read-only block
- **Coherence miss**
  - Miss to a block evicted by another processor’s requests

Making the cache larger…

- Doesn’t reduce these type of misses
- As cache grows large, these sorts of misses dominate

**False sharing**

- Two or more processors sharing parts of the same block
- But *not* the same bytes within that block (no actual sharing)
- Creates pathological “ping-pong” behavior
- Careful data placement may help, but is difficult
More Cache Coherence

In reality: many coherence protocols

• Snooping: VI, MSI, MESI, MOESI, …
  - But Snooping doesn’t scale
• Directory-based protocols
  - Caches & memory record blocks’ sharing status in directory
  - Nothing is free → directory protocols are slower!

Cache Coherency:
• requires that reads return most recently written value
• Is a hard problem!
Informally, Cache Coherency requires that reads return most recently written value.

Cache coherence hard problem.

Snooping protocols are one approach.
Next Goal: Synchronization

Is cache coherency sufficient?

i.e. Is cache coherency *(what values are read)* sufficient to maintain consistency *(when a written value will be returned to a read)*. Both coherency and consistency are required to maintain consistency in shared memory programs.
Are We Done Yet?

Thread A
lw t0, r3, 0
ADDIU t0, t0, 1
sw t0, x, 0
ADDIU t0, t0, 1

Thread B
lw t0, r3, 0
ADDIU t0, t0, 1
sw t0, x, 0

What just happened???
Is Cache Coherency Protocol Broken??
Clicker Question

The Previous example shows us that

a) Caches can be incoherent even if there is a coherence protocol.
b) Cache coherence protocols are not rich enough to support multi-threaded programs.
c) Coherent caches are not enough to guarantee expected program behavior.
d) Multithreading is just a really bad idea.
e) All of the above
The Previous example shows us that

a) Caches can be incoherent even if there is a coherence protocol.
b) Cache coherence protocols are not rich enough to support multi-threaded programs
c) Coherent caches are not enough to guarantee expected program behavior.
d) Multithreading is just a really bad idea.
e) All of the above
Programming with Threads

Need it to exploit multiple processing units
...to parallelize for multicore
...to write servers that handle many clients

Problem: hard even for experienced programmers
• Behavior can depend on subtle timing differences
• Bugs may be impossible to reproduce

Needed: synchronization of threads
Programming with Threads

Within a thread: execution is sequential

Between threads?
  • No ordering or timing guarantees
  • Might even run on different cores at the same time

Problem: hard to program, hard to reason about
  • Behavior can depend on subtle timing differences
  • Bugs may be impossible to reproduce

Cache coherency is not sufficient…
Need explicit synchronization to make sense of concurrency!
Programming with Threads

Concurrency poses challenges for:

**Correctness**
- Threads accessing shared memory should not interfere with each other

**Liveness**
- Threads should not get stuck, should make forward progress

**Efficiency**
- Program should make good use of available computing resources (e.g., processors).

**Fairness**
- Resources apportioned fairly between threads
Example: Multi-Threaded Program

Apache web server

```c
void main() {
    setup();
    while (c = accept_connection()) {
        req = read_request(c);
        hits[req]++;
        send_response(c, req);
    }
    cleanup();
}
```
Example: web server

Each client request handled by a separate thread (in parallel)
  • Some shared state: hit counter, ...

Thread 52
read hits
addiu
write hits

Thread 205
read hits
addiu
write hits

(look familiar?)

• Timing-dependent failure ⇒ race condition
  • hard to reproduce ⇒ hard to debug
Two threads, one counter

Possible result: lost update!

Timing-dependent failure ⇒ race condition
• Very hard to reproduce ⇒ Difficult to debug
Race conditions

Timing-dependent error involving access to shared state

Race conditions depend on how threads are scheduled
  • i.e. who wins “races” to update state

Challenges of Race Conditions
  • Races are intermittent, may occur rarely
  • Timing dependent = small changes can hide bug

Program is correct only if all possible schedules are safe
  • Number of possible schedules is huge
  • Imagine adversary who switches contexts at worst possible time
Critical Sections

What if we can designate parts of the execution as **critical sections**

- Rule: only one thread can be “inside” a critical section

Thread 52

```text
CSEnter()
read hits
addi
write hits
CSExit()
```

Thread 205

```text
CSEnter()
read hits
addi
write hits
CSExit()
```
Critical Sections

To eliminate races: use *critical sections* that only one thread can be in

- Contending threads must wait to enter

```plaintext
CSEnter();
Critical section
CSExit();
```
Mutual Exclusion Lock (Mutex)

Implement **CSEnter** and **CSExit**; ie. a critical section
Only one thread can hold the lock at a time
“**I have the lock**”

Mutual Exclusion Lock (mutex)
lock(m): wait till it becomes free, then lock it
unlock(m): unlock it

```c
safe_increment() {
    pthread_mutex_lock(&m);
    hits = hits + 1;
    pthread_mutex_unlock(&m);
}
```
Mutexes

Only one thread can hold a given mutex at a time
Acquire (lock) mutex on entry to critical section
  • Or block if another thread already holds it
Release (unlock) mutex on exit
  • Allow one waiting thread (if any) to acquire & proceed

```c
pthread_mutex_init(&m);  // Init
pthread_mutex_lock(&m);  // T1
hits = hits+1;           // # wait
pthread_mutex_unlock(&m); // T2

pthread_mutex_lock(&m);  // T1
hits = hits+1;           // # wait
pthread_mutex_unlock(&m); // T2
```

Next Goal

How to implement mutex locks?
What are the hardware primitives?

Then, use these mutex locks to implement critical sections, and use critical sections to write parallel safe programs
Hardware Support for Synchronization

Atomic read & write memory operation
  • Between read & write: *no writes to that address*

Many atomic hardware primitives
  • test and set (x86)
  • atomic increment (x86)
  • bus lock prefix (x86)
  • compare and exchange (x86, ARM deprecated)
  • linked load / store conditional (pair of insns) (RISC-V, ARM, PowerPC, DEC Alpha, …)
Synchronization in RISC-V

Load Reserved: \( LR.W \ rd, \ rs_1 \)
“I want the value at address X. Also, start monitoring any writes to this address.”

Store Conditional: \( SC.W \ rd, \ rs_1, \ rs_2 \)
\( SC.W \ rd, \ rs_2, (rs_1) \)
“If no one has changed the value at address X since the \( LR.W \), perform this store and tell me it worked.”

- Data at location has not changed since the LR?
  - SUCCESS:
    • Performs the store (\( rs_2 \) to the address, \( rs_1 \) is the value)
    • Returns 0 in \( rd \)
  - FAILURE:
    • Does not perform the store
    • Returns 1 in \( rd \)
Synchronization in RISC-V

Load Reserved: \( \text{LR. Wrd, rs1} \)
Store Conditional: \( \text{SC. Wrd, rs1, rs2} \)
\( \text{SC. Wrd, rs2, (rs1)} \)

- Succeeds if location not changed since the LR
  - Returns 0 in rd
- Fails if location is changed
  - Returns 1 in rd

Any time a processor intervenes and modifies the value in memory between the LR and SC instruction, the SC returns 1 in rd, causing the code to try again.
  i.e. use this value 1 in rd to try again.
Synchronization in RISC-V

Load Reserved:          LR. W rd, rs1
Store Conditional:     SC. W rd, rs1, rs2
                      SC. W rd, rs2, (rs1)

- Succeeds if location not changed since the LR
  - Returns 1 in rd
- Fails if location is changed
  - Returns 0 in rd

Example: atomic incrementor

```
atomic(i++)
```

```
try:
  LR.W t0, (s0)
  ADDIU t0, t0, 1
  SC.W t0, t0, (s0)
  BNEZ t0, try
```

```
i++
```

```
LW t0, s0, 0
ADDIU t0, t0, 1
SW t0, s0, 0
```

Value in memory changed between LR and SC?
→ SC returns 0 in t0 → retry
## Atomic Increment in Action

Now we can write parallel and correct programs

Thread A
for(int i = 0, i < 5; i++) {
    j++;}
    mutex_lock(m);
    x = x + 1;
    mutex_unlock(m);
}

Thread B
for(int j = 0; j < 5; j++)
    mutex_lock(m);
    x = x + 1;
    mutex_unlock(m);
}
Alternative Atomic Instructions

Other atomic hardware primitives
- test and set (x86)
- atomic increment (x86)
- bus lock prefix (x86)
- compare and exchange (x86, ARM deprecated)
- load reserved / store conditional
  (RISC-V, ARM, PowerPC, DEC Alpha, …)
Synchronization

Synchronization techniques

**clever code**
- must work despite adversarial scheduler/interrupts
- used by: hackers
- also: noobs

**disable interrupts**
- used by: exception handler, scheduler, device drivers, ...

**disable preemption**
- dangerous for user code, but okay for some kernel code

**mutual exclusion locks (mutex)**
- general purpose, except for some interrupt-related cases
Summary

Need parallel abstractions, especially for multicore

Writing correct programs is hard
   Need to prevent data races

Need critical sections to prevent data races
   Mutex, mutual exclusion, implements critical section
   Mutex often implemented using a lock abstraction

Hardware provides synchronization primitives such as LR and SC (load reserved and store conditional) instructions to efficiently implement locks
Next Goal

How do we use synchronization primitives to build concurrency-safe data structure?
Producer/Consumer Example (1)

Access to **shared data** must be synchronized

- Goal: enforce datastructure **invariants**

```c
// invariant:
// data is in A[h ... t-1]
char A[100];
int h = 0, t = 0;

// producer: add to list tail
void put(char c) {
    A[t] = c;
    t = (t+1)%n;
}
```
Producer/Consumer Example (1)

Access to **shared data** must be synchronized
- Goal: enforce datastructure *invariants*

```c
// invariant:
// data is in A[h ... t-1]
char A[100];
int h = 0, t = 0;

// producer: add to list tail // consumer: take from list head
void put(char c) {
    A[t] = c;
    t = (t+1)%n;
}

char get() {
    while (h == t) {};
    char c = A[h];
    h = (h+1)%n;
    return c;
}
```
Producer/Consumer Example (1)

Access to **shared data** must be synchronized

- Goal: enforce datastructure invariants

```c
// invariant:
// data is in A[h ... t-1]
char A[100];
int h = 0, t = 0;

// producer: add to list tail
// consumer: take from list head
void put(char c) {
    A[t] = c;
    t = (t+1)%n;
}
char get() {
    while (h == t) {
    }
    char c = A[h];
    h = (h+1)%n;
    return c;
}
```

What is wrong with code?

a) Will lose update to $t$ and/or $h$
b) Invariant is not upheld
c) Will produce if full
d) Will consume if empty
e) All of the above
Producer/Consumer Example (1)

Access to **shared data** must be synchronized

- Goal: enforce datastructure **invariants**

```c
// invariant:
// data is in A[h ... t-1]
char A[100];
int h = 0, t = 0;

// producer: add to list tail // consumer: take from list head
void put(char c) {
    A[t] = c;
    t = (t+1)%n;
}

char get() {
    while (h == t) { }
    char c = A[h];
    h = (h+1)%n;
    return c;
}
```

What is wrong with the code?

**Could miss an update** to `t` or `h`

**Breaks invariant:** only produce if not full and only consume if not empty

⇒ **Need to synchronize access to shared data**
Producer/Consumer Example (1)

Access to **shared data** must be synchronized
- Goal: enforce data structure **invariants**

```c
// invariant:
// data is in A[h ... t-1]
char A[100];
int h = 0, t = 0;

// producer: add to list tail
void put(char c) {
    A[t] = c;
    t = (t+1)%n;
    acquire-lock();
    release-lock();
}

// consumer: take from list head
char get() {
    while (h == t) {
    }
    char c = A[h];
    h = (h+1)%n;
    acquire-lock();
    return c;
    release-lock();
}
```

**Rule of thumb:** all access and updates that can affect invariant become critical sections
Protecting an invariant Example (2)

// invariant: (protected by mutex m)
// data is in A[h ... t-1]

pthread_mutex_t *m = pthread_mutex_create();
char A[100];
int h = 0, t = 0;

// producer: add to list tail
void put(char c) {
    pthread_mutex_lock(m);
    A[t] = c;
    t = (t+1)%n;
    pthread_mutex_unlock(m);
}

// consumer: take from list head
char get() {
    pthread_mutex_lock(m);
    while(h == t) {}  // wait for data
    char c = A[h];
    h = (h+1)%n;
    pthread_mutex_unlock(m);
    return c;
}

Rule of thumb: all access and updates that can affect invariant become critical sections
Protecting an invariant Example (2)

// invariant: (protected by mutex m)
// data is in A[h ... t-1]

pthread_mutex_t *m = pthread_mutex_create();
char A[100];
int h = 0, t = 0;

// producer: add to list tail
void put(char c) {
    pthread_mutex_lock(m);
    A[t] = c;
    t = (t+1)%n;
    pthread_mutex_unlock(m);
}

// consumer: take from list head
char get() {
    pthread_mutex_lock(m);
    while(h == t) {} // fixed
    char c = A[h];
    h = (h+1)%n;
    pthread_mutex_unlock(m);
    return c;
}

Does this fix work?

BUG: Can’t wait while holding lock

Rule of thumb: all access and updates that can affect
invariant become critical sections
Guidelines for successful mutexing

Insufficient locking can cause races
- Skimping on mutexes? Just say no!

Poorly designed locking can cause deadlock
- P1: lock(m1); lock(m2); lock(m2); lock(m1);
- Know why you are using mutexes!
- Acquire locks in a consistent order to avoid cycles
- Use lock/unlock like braces (match them lexically)
  - lock(&m); ...; unlock(&m)
  - Watch out for return, goto, and function calls!
  - Watch out for exception/error conditions!
Beyond mutexes Example (3)

Writers must check for full buffer & Readers must check for empty buffer
  • ideal: don’t busy wait… go to sleep instead

```c
char get() {
  acquire(L);
  char c = A[h];
  h = (h+1)%n;
  release(L);
  return c;
}
```

while(empty) {}
Beyond mutexes Example (3)

Writers must check for full buffer & Readers must check for empty buffer
- ideal: don’t busy wait… go to sleep instead

```java
char get() {
    acquire(L);
    while (h == t) { }
    char c = A[h];
    h = (h+1)%n;
    release(L);
    return c;
}
```

Dilemma: Have to check while holding lock,
Beyond mutexes Example (3)

Writers must check for full buffer & Readers must check for empty buffer

- ideal: don’t busy wait... go to sleep instead

```c
char get() {
    acquire(L);
    while (h == t) { }
    char c = A[h];
    h = (h+1)%n;
    release(L);
    return c;
}
```

Dilemma: Have to check while holding lock, but cannot wait while hold lock

Cannot check condition while Holding the lock, BUT, empty condition may no longer hold in critical section

```
head
empty
```

```
last==head
```
Beyond mutexes Example (4)

Writers must check for full buffer & Readers must check for empty buffer

- ideal: don’t busy wait… go to sleep instead

```c
char get() {
  do {
    acquire(L);
    empty = (h == t);
    if (!empty) {
      c = A[h];
      h = (h+1)%n;
    }
    release(L);
  } while (empty);
  return c;
}
```

Does this work?

- a) Yes
- b) No
Beyond mutexes Example (4)

Writers must check for full buffer & Readers must check for empty buffer

• ideal: don’t busy wait… go to sleep instead

```c
char get() {
    do {
        acquire(L);
        empty = (h == t);
        if (!empty) {
            c = A[h];
            h = (h+1)%n;
        }
        release(L);
    } while (empty);
    return c;
}
```

It works.
But, it is wasteful
Due to the spinning
Language-level Synchronization
Condition variables

Use [Hoare] a **condition variable** to wait for a condition to become true (without holding lock!)

```
wait(m, c) :
• atomically release m and sleep, waiting for condition c
• wake up holding m sometime after c was signaled
signal(c) : wake up one thread waiting on c
broadcast(c) : wake up all threads waiting on c
```

POSIX (e.g., Linux): pthread_cond_wait, pthread_cond_signal, pthread_cond_broadcast
Using a condition variable Example (5)

wait(m, c) : release m, sleep until c, wake up holding m
signal(c) : wake up one thread waiting on c

void put(char c) {
    lock(m);
    while ((t-h) % n == 1)
        wait(m, not_full);
    A[t] = c;
    t = (t+1) % n;
    unlock(m);
    signal(not_empty);
}

char get() {
    lock(m);
    while (t == h)
        wait(m, not_empty);
    char c = A[h];
    h = (h+1) % n;
    unlock(m);
    signal(not_full);
    return c;
}
Monitors

A **Monitor** is a concurrency-safe datastructure, with…

- one mutex
- some condition variables
- some operations

All operations on monitor acquire/release mutex

- one thread in the monitor at a time

Ring buffer was a monitor
Java, C#, etc., have built-in support for monitors
Java concurrency

Java objects can be monitors

- “synchronized” keyword locks/releases the mutex
- Has one (!) builtin condition variable
  - o.wait() = wait(o, o)
  - o.notify() = signal(o)
  - o.notifyAll() = broadcast(o)

- Java wait() can be called even when mutex is not held. Mutex not held when awoken by signal(). Useful?
Language-level Synchronization

Lots of synchronization variations…

**Reader/writer locks**
- Any number of threads can hold a read lock
- Only one thread can hold the writer lock

**Semaphores**
- N threads can hold lock at the same time

**Monitors**
- Concurrency-safe data structure with 1 mutex
- All operations on monitor acquire/release mutex
- One thread in the monitor at a time

**Message-passing, sockets, queues, ring buffers, …**
- transfer data and synchronize
Summary
