Lecture 16: Instruction Selection Algorithms
28 Feb 00

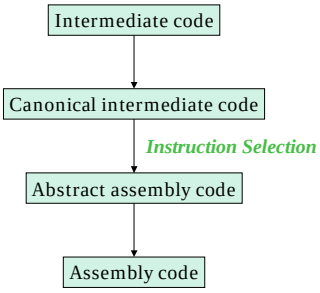
Administration

- Prelim review tonight 7-9PM
- Prelim Wednesday in class

Outline

- Tiles: review
- How to implement Maximal Munch
- Some tricky tiles
  - conditional jumps
  - instructions with hard-wired effects
- Optimum instruction selection: dynamic programming

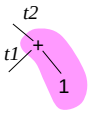
Where we are



Instruction Selection

- Current step: converting canonical intermediate code into abstract assembly
  - implement each IR statement with a sequence of one or more assembly instructions
  - sub-trees of IR statement are broken into *tiles* associated with one or more assembly instructions

Tiles

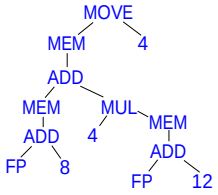


mov t2, t1
add t2, *imm8*

- Tiles capture compiler's understanding of instruction set
- Each tile: sequence of instructions that update a fresh temporary (may need extra mov's) and associated IR tree
- All outgoing edges are temporaries

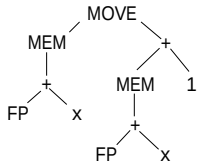
Maximal Munch Algorithm

- Assume larger tiles = better
- Greedy algorithm: start from top of tree and use largest tile that matches tree
- Tile remaining subtrees recursively



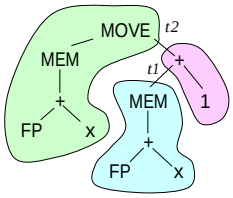
Another example

x = x + 1;



Example

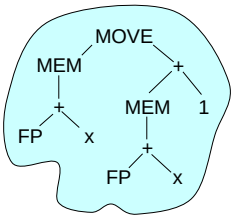
x = x + 1;



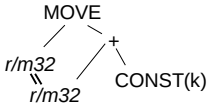
```
mov t1, [bp+x]
mov t2, t1
add t2, 1
mov [bp+x], t2
```

Alternate (non-RISC) tiling

x = x + 1;



```
add [bp+x], 1
```

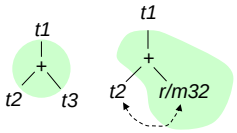


How good is it?

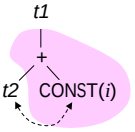
- *Very* rough approximation on modern pipelined architectures: execution time is number of tiles
- Maximal munch finds an *optimal* but not necessarily *optimum* tiling: cannot combine two tiles into a lower-cost tile

ADD expression tiles

```
mov t1, t2
add t1, r/m32
```



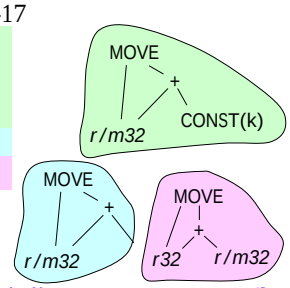
```
mov t1, t2
add t1, imm32
```



ADD statement tiles

Intel Architecture Manual, Vol 2, 3-17

```
add eax, imm32
add r/m32, imm32
add r/m32, imm8
add r/m32, r32
add r32, r/m32
```



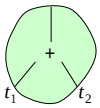
Designing tiles

- Only add tiles that are useful to compiler
- Many instructions will be too hard to use effectively or will offer no advantage
- Need tiles for all single-node trees to guarantee that every tree can be tiled, e.g.

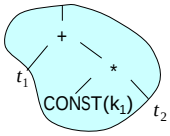
```
mov t1, t2
add t1, t3
```

More handy tiles

lea instruction computes a memory address but doesn't actually load from memory



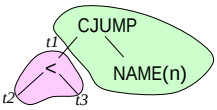
`lea t_f, [t_1+t_2]` (`t_f` a *fresh* temporary)



`lea t_f, [t_1+k_1*t_2]` (`k_1` one of 2,4,8,16)

Matching CJUMP for RISC

- As defined in lecture, have
  CJUMP(*cond*, *destination*)
- Appel: CJUMP(*op*, *e1*, *e2*, *destination*) where *op* is one of ==, !=, <, <=, =>, >
- Our CJUMP translates easily to RISC ISAs that have explicit comparison instructions

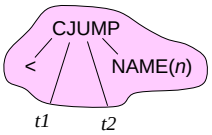


MIPS

```
cmplt t2, t3, t1
br    t1, n
```

Condition code ISA

- Appel's CJUMP corresponds more directly to Pentium conditional jumps

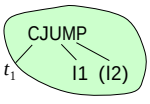


```
cmp t1, t2
jl n
```

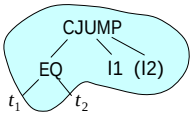
- However, can handle Pentium-style jumps with lecture IR with appropriate tiles

Branches

- How to tile a conditional jump?
- Fold comparison operator into tile



```
test t1
jnz l1
```



```
cmp t1, t2
je l1
```

Fixed-register instructions

mul *r/m32*

Sets eax to low 32 bits of eax * operand, edx to high 32 bits

jecxz *label*

Jump to *label* if ecx is zero

add eax, *r/m32*

Add to eax

Strategies for fixed regs

- Use extra mov's and temporaries

```
mov eax, t2
mul t3
mov t1, eax
```

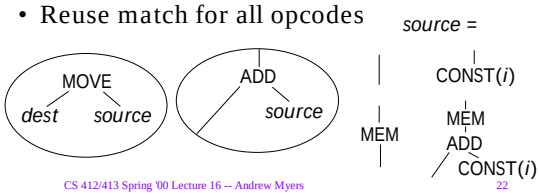
- Don't use instruction (jecxz)
- Let assembler figure out when to use (add eax, ...)

Implementation

- Maximal Munch: start from statement node
- Find largest tile covering top node and matching all children
- Invoke recursively on all children of *tile*
- Generate code for this tile (code for children will have been generated already in recursive calls)
- How to find matching tiles?

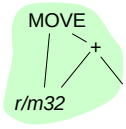
Implementing tiles

- Explicitly building every possible tile: tedious
- Easier to write subroutines for matching Pentium source, destination operands
- Reuse match for all opcodes



Matching tiles

```
abstract class IR_Stmt {
   Assembly munch();
}
class IR_Move extends IR_Stmt {
   IR_Expr src, dst;
   Assembly munch() {
        if (src instanceof IR_Plus &&
          ((IR_Plus)src).lhs.equals(dst) &&
          is_regmem32(dst) {
            Assembly e = ((IR_Plus)src).rhs.munch();
            return e.append(new AddIns(dst,
                                e.target())); }
        else if …
   }
}
```



Tile Specifications

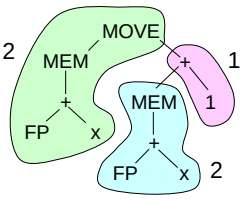
- Previous approach simple, efficient, but hard-codes tiles and their priorities
- Another option: explicitly create data structures representing each tile in instruction set
- Tiling performed by a generic tree-matching and code generation procedure
- For RISC instruction sets, over-engineering

Improving instruction selection

- Because greedy, Maximal Munch does not necessarily generate best code
- Always selects largest tile, not necessarily fastest instruction
- May pull nodes up into tiles inappropriately – better to leave in lower tile
- Can do better using *dynamic programming* algorithm

Timing model

- Idea: associate *cost* with each tile (proportional to # cycles to execute)
- Estimate of total execution time is sum of costs of all tiles

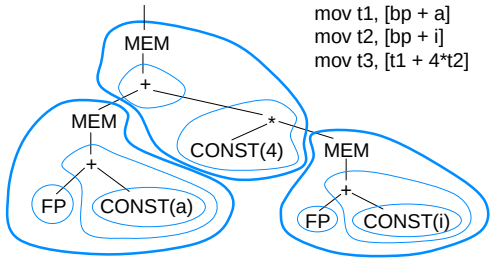


Total cost: 5

Finding optimum tiling

- **Goal:** find minimum total cost tiling of tree
- **Algorithm:** for *every* node, find minimum total cost tiling of that node and sub-tree.
- **Lemma:** once minimum cost tiling of all children of a node is known, can find minimum cost tiling of the node by trying out all possible tiles matching the node
- **Therefore:** start from leaves, work *upward* to top node

Dynamic programming: a[i]

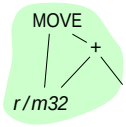


Recursive implementation

- Any dynamic programming algorithm equivalent to a *memoized* version of same algorithm that runs top-down
- For each node, record best tile for node
- Start at top, recurse:
  - First, check in table for best tile for this node
  - If not computed, try each matching tile to see which one has lowest cost
  - Store lowest-cost tile in table and return
- Finally, use entries in table to emit code

Max Munch → Memoization

```
class IR_Move extends IR_Stmt {
  IR_Expr src, dst;
  Assembly best; // initialized to null
  int optTileCost() {
    if (best != null) return best.cost();
    if (src instanceof IR_Plus &&
      ((IR_Plus)src).lhs.equals(dst) && is_regmem32(dst)) {
      int src_cost = ((IR_Plus)src).rhs.optTileCost();
      int cost = src_cost + CISC_ADD_COST;
      if (cost < best.cost())
          best = new AddIns(dst, e.target); }
    ...consider all other tiles...
    return best.cost();
  }
}
```



Problems with model

- Modern processors:
  - execution time *not* sum of tile times
  - instruction order matters
    - Processors is *pipelining* instructions and executing different pieces of instructions in parallel
    - bad ordering (e.g. too many memory operations in sequence) stalls processor pipeline
    - processor can execute some instructions in parallel (super-scalar)

Summary

- Can specify code generation process as a set of tiles that relate IR trees to instruction sequences
- Instructions using fixed registers problematic but can be handled using extra temporaries
- **Maximal Munch** algorithm implemented simply as recursive traversal
- Dynamic programming algorithm generates better code, also can be implemented recursively using **memoization**
- Real optimization will require *instruction scheduling* (assembler may do this for us)
