

## CS 412 Introduction to Compilers

Andrew Myers  
Cornell University

Lecture 28: Dataflow analysis frameworks  
9 Apr 01

## Administration

- Homework 4 due Friday the 13<sup>th</sup>
- Prelim April 17, 7:30PM-9:30PM
  - static semantics, IR and assembly code generation, object-oriented languages, data-flow analysis, optimization

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

2

## Available expressions

- Idea: want to perform common subexpression elimination

$a = x+1$   
 $\dots$   
 $b = x+1$

$a = x+1$   
 $\dots$   
 $b = a$

- Transformation is safe if original  $x+1$  is an *available expression* (still computes same value)

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

3

## Dataflow values

- Let  $in[n]$ ,  $out[n]$  be sets of nodes whose computed expression is available at  $n$

$n$	$gen[n]$	$kill[n]$
$a=b \text{ OP } c$	$\{n\} - kill[n]$	$uses(a)$
$a=[b]$	$\{n\} - kill[n]$	$uses(a)$
$[a]=b$	$\{\}$	$uses(x)$
		(for all $x$ that may be equal to $a$ )
$a=f(b_1, \dots, b_n)$	$\{\}$	$uses(x)$ (for all $x$ )
<i>other</i>	$\{\}$	$\{\}$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

4

## Constraints

$out[n] \supseteq gen[n]$

“An expression made available by  $n$  at least reaches  $n$ 's output”

$in[n'] \subseteq out[n]$  (if  $n'$  is succ. of  $n$ )

“An expression is available at  $n'$  only if it is available at every predecessor  $n$ ”

$out[n] \cup kill[n] \supseteq in[n]$

“An expression available on input is either available on output or killed”

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

5

## Dataflow equations

$out[n] \supseteq gen[n]$

$in[n'] \subseteq out[n]$  (if  $n'$  is succ. of  $n$ )

$out[n] \cup kill[n] \supseteq in[n]$

Equations for iterative solution:

$out[n] = gen[n] \cup (in[n] - kill[n])$

$in[n'] = \bigcap_{n \in \text{pred}[n']} out[n]$

$\square = \bigcap$  Starting condition:

$in[n]$  is set of *all* nodes

$in[start] = \emptyset$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

6

## Dataflow analysis

- Propagates information about program through flowgraph. Dataflow values make up space  $L$
- Solution:  $in[n], out[n] \in L$  for every node  $n$
- Live variable analysis: set of live variables
- Available expressions: set of available exprs

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

7

## Dataflow analysis framework

Dataflow analysis characterized by:

1. Space of values  $L$
2. Flow function  $F_n$  for every node  $n$   
 $out[n] = F_n(in[n])$   
 $F_n: L \rightarrow L$

“If  $I \in L$  is true before executing node  $n$ ,  
 $F_n(I)$  is true afterward”

All analyses so far:  $F_n(I) = gen[n] \cup (I - kill[n])$   
 Live vars:  $F_n(I) = use[n] \cup (I - def[n])$   
 ( $gen=use, kill=def$ )

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

8

## Combining operator

1. Space of values  $L$
2. Flow function  $F_n$  for every node  $n$
3. Combining operator  $\sqcap$

“If we know either  $I_1$  or  $I_2$  holds on entry to  $n$ , we know at most  $I_1 \sqcap I_2$ ”

$$in[n] = \sqcap_{n' \in pred[n]} out[n']$$

live vars:  $\sqcap = \cup$  avail exprs:  $\sqcap = \cap$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

9

## Iterative analysis

for all  $n$ ,  $in[n] = out[n] = \top$  4. maximum information  $\top \in L$   
 repeat until no change  
 for all  $n$   
 $in[n] = \sqcap_{n' \in pred[n]} out[n']$   
 $out[n] = F_n(in[n])$   
 end  
 end

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

10

## Questions

Will iterative analysis

- produce a solution when it terminates?
  - produce the best solution possible?
  - terminate?
- Depends on properties of  $L, F_n, \sqcap$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

11

## $L$ as partial order

- Best solution has as much information as possible – allows most optimization
  - Live variables: smallest possible set
  - Available expressions: largest possible set
- Some dataflow values contain more information:  $I_1 \sqsubseteq I_2$  if  $I_2$  has at least as much information as  $I_1$
- Live variables:  $I_1 \sqsubseteq I_2 \Leftrightarrow I_1 \supseteq I_2$
- Available expressions:  $I_1 \sqsubseteq I_2 \Leftrightarrow I_1 \subseteq I_2$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

12

## Partial orders

- L is a *partial order* defined by ordering relation  $\sqsubseteq$
- Some elements are incomparable
- Properties of a partial order
  - $x \sqsubseteq x$  (reflexive)
  - $x \sqsubseteq y \wedge y \sqsubseteq z \Rightarrow x \sqsubseteq z$  (transitive)
  - $x \sqsubseteq y \wedge y \sqsubseteq x \Rightarrow x = y$  (anti-symmetry)
- Examples: integers ordered by  $\leq$ , types ordered by  $<:$ , sets ordered by  $\subseteq$  or  $\supseteq$ .

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

13

## Example: subsets of {a,b,c}

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

14

## Greatest lower bound

- Combining operator  $I_1 \sqcap I_2$  gives element  $I$  such that  $I \sqsubseteq I_1, I \sqsubseteq I_2$
- $I$  is a *lower bound* for  $I_1, I_2$  (consistent with both)
- Want *greatest* such element (most info): *greatest lower bound* (GLB)
- Partial order with GLB/meet ( $\sqcap$ ) and LUB/join ( $\sqcup$ ) is a *lattice*
- With only GLB, a *lower semilattice*

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

15

## Meet-over-paths solution

- Consider traversal of flowgraph visiting nodes  $a, b, c, \dots, n$
- Assume  $I_0$  is initial information
- Knowable information is  $F_n(\dots(F_c(F_b(F_a(I_0)))))$
- Best possible solution is  $I$  such that  $I \sqsubseteq F_n(\dots(F_c(F_b(F_a(I_0)))))$  for *all* paths  $a, b, c, \dots, n$
- MOP (meet-over-paths) soln:

$$\sqcap_{\text{all paths } p} F_{p_1}(F_{p_2}(F_{p_3}(\dots)))$$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

16

## Data-flow equations

- Algorithm repeatedly recomputes each  $out[n]$  as  $F_n(\sqcap_{n' \in pred[n]} out[n'])$
- Let  $x_1 \dots x_n$  be  $out[1] \dots out[n]$ . Algorithm:
  - $x_i = F_i(\sqcap_{j \in pred[i]} x_j)$
- Solution is point in  $L^n$ :  $\mathbf{X} = (x_1, \dots, x_n)$
- Total set of equations is  $\mathbf{X} = \mathbf{F}(\mathbf{X})$  where  $\mathbf{F}(\mathbf{X}) = (F_1(\sqcap_{j \in pred[1]} x_j), F_2(\sqcap_{j \in pred[2]} x_j), \dots)$
- Any solution to constraints is *fixed point* of  $\mathbf{F}$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

17

## Fixed points

- Iterative analysis: initialize all  $x_i$  with top of lattice ( $\mathbf{X}_0 = (\tau, \tau, \tau, \dots)$ ), apply  $\mathbf{F}(\mathbf{X})$  until fixed point is reached:  $\mathbf{F}^k(\mathbf{X}_0) = \mathbf{F}^{k+1}(\mathbf{X}_0)$
- $\mathbf{F}^k(\mathbf{X}_0)$  is a fixed point of  $F$ : a value that  $F$  maps to itself
- Wanted: maximal fixed point

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

18

## Monotonicity

- Flow functions map lattice values to other lattice values; must be *monotonic*
- Monotonicity:
 
$$I_1 \sqsubseteq I_2 \Rightarrow F(I_1) \sqsubseteq F(I_2)$$
 “If you have more information entering a node, you have at least as much leaving”
- Example: *reaching definitions*. Lattice is all sets of defining nodes ordered by subset relation:
 
$$F_n(x) = \text{gen}[n] \sqcup (x - \text{kill}[n])$$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

19

## Termination

- First step either lowers some  $x_i$  or terminates
- Second step sees same  $x_i$  as first step ( $\top$ ), or possibly lower:  $F(\mathbf{X}_0) \sqsubseteq \mathbf{X}_0$
- Monotonicity  $I_1 \sqsubseteq I_2 \Rightarrow F(I_1) \sqsubseteq F(I_2)$   
 $\Rightarrow$  output of second step  $F^2(\mathbf{X}_0)$  is lower than first step (or it terminates):  $F^2(\mathbf{X}_0) \sqsubseteq F^1(\mathbf{X}_0)$
- Induction: each iteration moves at least one node lower in lattice:  $F^{i+1}(\mathbf{X}_0) \sqsubseteq F^i(\mathbf{X}_0)$
- # algorithm steps to fixed point is at most *height* of lattice  $H$  times number of nodes  $n$ :  $k = O(nH)$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

20

## Solution quality

- MOP is best possible solution:
 
$$\sqcap_{\text{all paths } p} F_{p1}(F_{p2}(F_{p3}(\dots)))$$
- Does iterative analysis
 
$$x_i = F_i(\sqcap_{j \in \text{pred}[i]} x_j)$$
 produce the MOP solution?
- Yes, if flow functions *distribute* over the meet operator:

$$\sqcap_i F_n(x_i) = F_n(\sqcap_i x_i)$$

- Not all analyses give MOP solution!**

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

21

## Reaching definitions

- $L$  is all sets of defining nodes in call flow graph. Maximum information means *smallest possible* lists of reaching definitions, so:
- Top ( $\top$ ) is the empty set  $\{ \}$ , meet ( $\sqcap$ ) is set union ( $\cup$ )
 
$$x_n = \text{out}[n]$$

$$F_n(x) = \text{gen}[n] \cup (x - \text{kill}[n])$$

$$x_i = F_i(\sqcap_{j \in \text{pred}[i]} x_j) \Leftrightarrow \begin{aligned} \text{in}[n] &= \cup_{n' \in \text{prev}[n]} \text{out}[n'] \\ \text{out}[n] &= \text{gen}[n] \cup (\text{in}[n] - \text{kill}[n]) \end{aligned}$$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

22

## Monotonic?

$$F_n(x) = \text{gen}[n] \cup (x - \text{kill}[n])$$

$$x_1 \sqcap x_2 = x_1 \cup x_2$$

$$x \sqsubseteq y \Leftrightarrow x \supseteq y$$

- Is  $F_n(x)$  monotonic?
 
$$F_n(x) = \text{gen}[n] \cup (x - \text{kill}[n])$$

$$F_n(x \cup y) = \text{gen}[n] \cup ((x \cup y) - \text{kill}[n]) = \text{gen}[n] \cup (x - \text{kill}[n]) \cup (y - \text{kill}[n]) = F_n(x) \cup (y - \text{kill}[n])$$

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

23

## MOP?

$$F_n(x) = \text{gen}[n] \cup (x - \text{kill}[n])$$

$$x_1 \sqcap x_2 = x_1 \cup x_2$$

- Does  $F_n(x)$  distribute over  $\sqcap$ ?
 
$$F_n(x \sqcap y) = F_n(x \cup y) = \text{gen}[n] \cup ((x \cup y) - \text{kill}[n]) = (\text{gen}[n] \cup (x - \text{kill}[n])) \cup (\text{gen}[n] \cup (y - \text{kill}[n])) = F_n(x) \cup F_n(y) = F_n(x) \sqcap F_n(y)$$

$\therefore$  Iterative analysis always terminates, finds the best possible (meet-over-paths) solution to reaching definitions

Lecture 28 CS 412/413 Spring '01 -- Andrew Myers

24

## Other analyses

- Live variables

$$F_n(l) = use[n] \cup (l - def[n])$$

$\sqcap = \cup$

- Available expressions

$$F_n(l) = gen[n] \cup (l - kill[n])$$

$\sqcap = \cap$

- Computes MOP solutions?

## Summary

- Analyses for standard optimizations fit into dataflow analysis framework
- Iterative analysis finds solution if flow function monotonic in  $\sqsubseteq$ , combining function  $\sqcap$  defines lower semilattice
- Solution is MOP if distribution condition  $\sqcap_i F(x_i) = F(\sqcap_i x_i)$  holds
