NOTE: The IA-32 Intel Architecture Software Developer’s Manual consists of three volumes: Basic Architecture, Order Number 245470; Instruction Set Reference, Order Number 245471; and the System Programming Guide, Order Number 245472. Please refer to all three volumes when evaluating your design needs.

About This Manual
CHAPTER 1
ABOUT THIS MANUAL

The IA-32 Intel Architecture Software Developer’s Manual, Volume 2: Instruction Set Reference (Order Number 245471) is part of a three-volume set that describes the architecture and programming environment of all IA-32 Intel® Architecture processors. The other two volumes in this set are:

The IA-32 Intel Architecture Software Developer’s Manual, Volume 1, describes the basic architecture and programming environment of an IA-32 processor; the IA-32 Intel Architecture Software Developer’s Manual, Volume 2, describes the instructions set of the processor and the opcode structure. These two volumes are aimed at application programmers who are writing programs to run under existing operating systems or executives. The IA-32 Intel Architecture Software Developer’s Manual, Volume 3, describes the operating-system support environment of an IA-32 processor, including memory management, protection, task management, interrupt and exception handling, and system management mode. It also provides IA-32 processor compatibility information. This volume is aimed at operating-system and BIOS designers and programmers.

1.1. IA-32 PROCESSORS COVERED IN THIS MANUAL

This manual includes information pertaining primarily to the most recent IA-32 processors, which include the Pentium® processor, the P6 family processors, and the Pentium® 4 processors. The P6 family processors are those IA-32 processors based on the P6 family micro-architecture. This family includes the Pentium® Pro, Pentium® II, and Pentium® III processors. The Pentium 4 processor is the first of a family of IA-32 processors based on the new Intel® NetBurst™ micro-architecture.

1.2. OVERVIEW OF THE IA-32 INTEL ARCHITECTURE SOFTWARE DEVELOPER’S MANUAL, VOLUME 2: INSTRUCTION SET REFERENCE

The contents of the IA-32 Intel Architecture Software Developer’s Manual, Volume 2 are as follows:

Chapter 1 — About This Manual. Gives an overview of all three volumes of the IA-32 Intel Architecture Software Developer’s Manual. It also describes the notational conventions in these
abouts this manual

manuals and lists related Intel manuals and documentation of interest to programmers and hardware designers.

Chapter 2 — Instruction Format. Describes the machine-level instruction format used for all IA-32 instructions and gives the allowable encodings of prefixes, the operand-identifier byte (ModR/M byte), the addressing-mode specifier byte (SIB byte), and the displacement and immediate bytes.

Chapter 3 — Instruction Set Reference. Describes each of the IA-32 instructions in detail, including an algorithmic description of operations, the effect on flags, the effect of operand- and address-size attributes, and the exceptions that may be generated. The instructions are arranged in alphabetical order. The general-purpose, x87 FPU, Intel MMX™ technology, Streaming SIMD Extensions (SSE), Streaming SIMD Extensions 2 (SSE2), and system instructions are included in this chapter.

Appendix A — Opcode Map. Gives an opcode map for the IA-32 instruction set.

Appendix B — Instruction Formats and Encodings. Gives the binary encoding of each form of each IA-32 instruction.

Appendix C — Intel C/C++ Compiler Intrinsics and Functional Equivalents. Lists the Intel C/C++ compiler intrinsics and their assembly code equivalents for each of the IA-32 MMX, SSE, and SSE2 instructions.

1.3. OVERVIEW OF THE IA-32 INTEL ARCHITECTURE SOFTWARE DEVELOPER’S MANUAL, VOLUME 1: BASIC ARCHITECTURE

The contents of this manual are as follows:

Chapter 1 — About This Manual. Gives an overview of all three volumes of the IA-32 Intel Architecture Software Developer’s Manual. It also describes the notational conventions in these manuals and lists related Intel manuals and documentation of interest to programmers and hardware designers.

Chapter 2 — Introduction to the IA-32 Architecture. Introduces the IA-32 architecture and the families of Intel processors that are based on this architecture. It also gives an overview of the common features found in these processors and brief history of the IA-32 architecture.

Chapter 3 — Basic Execution Environment. Introduces the models of memory organization and describes the register set used by applications.

Chapter 4 — Data Types. Describes the data types and addressing modes recognized by the processor; provides an overview of real numbers and floating-point formats and of floating-point exceptions.

Chapter 5 — Instruction Set Summary. Lists all the IA-32 architecture instructions, divided into technology groups (general-purpose, x87 FPU, MMX technology, SSE, SSE2, and system instructions). Within these groups, the instructions are presented in functionally related groups.
Chapter 6 — Procedure Calls, Interrupts, and Exceptions. Describes the procedure stack and the mechanisms provided for making procedure calls and for servicing interrupts and exceptions.

Chapter 7 — Programming With the General-Purpose and System Instructions. Describes the basic load and store, program control, arithmetic, and string instructions that operate on basic data types and on the general-purpose and segment registers; describes the system instructions that are executed in protected mode.

Chapter 8 — Programming With the x87 Floating Point Unit. Describes the x87 floating-point unit (FPU), including the floating-point registers and data types; gives an overview of the floating-point instruction set; and describes the processor’s floating-point exception conditions.

Chapter 9 — Programming with Intel MMX Technology. Describes the Intel MMX technology, including MMX registers and data types, and gives an overview of the MMX instruction set.

Chapter 10 — Programming with Streaming SIMD Extensions (SSE). Describes the SSE extensions, including the XMM registers, the MXCSR register, and the packed single-precision floating-point data types; gives an overview of the SSE instruction set; and gives guidelines for writing code that accesses the SSE extensions.

Chapter 11 — Programming with Streaming SIMD Extensions 2 (SSE2). Describes the SSE2 extensions, including XMM registers and the packed double-precision floating-point data types; gives an overview of the SSE2 instruction set; and gives guidelines for writing code that accesses the SSE2 extensions. This chapter also describes the SIMD floating-point exceptions that can be generated with SSE and SSE2 instructions, and it gives general guidelines for incorporating support for the SSE and SSE2 extensions into operating system and applications code.

Chapter 12 — Input/Output. Describes the processor’s I/O mechanism, including I/O port addressing, the I/O instructions, and the I/O protection mechanism.

Chapter 13 — Processor Identification and Feature Determination. Describes how to determine the CPU type and the features that are available in the processor.

Appendix A — EFLAGS Cross-Reference. Summarizes how the IA-32 instructions affect the flags in the EFLAGS register.

Appendix B — EFLAGS Condition Codes. Summarizes how the conditional jump, move, and byte set on condition code instructions use the condition code flags (OF, CF, ZF, SF, and PF) in the EFLAGS register.

Appendix C — Floating-Point Exceptions Summary. Summarizes the exceptions that can be raised by the x87 FPU floating-point and the SSE and SSE2 SIMD floating-point instructions.

Appendix D — Guidelines for Writing x87 FPU Exception Handlers. Describes how to design and write MS-DOS® compatible exception handling facilities for FPU exceptions, including both software and hardware requirements and assembly-language code examples. This appendix also describes general techniques for writing robust FPU exception handlers.

Appendix E — Guidelines for Writing SIMD Floating-Point Exception Handlers. Gives guidelines for writing exception handlers to handle exceptions generated by the SSE and SSE2 SIMD floating-point instructions.
1.4. OVERVIEW OF THE IA-32 INTEL ARCHITECTURE
SOFTWARE DEVELOPER’S MANUAL, VOLUME 3: SYSTEM
PROGRAMMING GUIDE

The contents of the *IA-32 Intel Architecture Software Developer's Manual, Volume 3* are as follows:

Chapter 1 — About This Manual. Gives an overview of all three volumes of the *IA-32 Software Developer’s Manual*. It also describes the notational conventions in these manuals and lists related Intel manuals and documentation of interest to programmers and hardware designers.

Chapter 2 — System Architecture Overview. Describes the modes of operation of an IA-32 processor and the mechanisms provided in the IA-32 architecture to support operating systems and executives, including the system-oriented registers and data structures and the system-oriented instructions. The steps necessary for switching between real-address and protected modes are also identified.

Chapter 3 — Protected-Mode Memory Management. Describes the data structures, registers, and instructions that support segmentation and paging and explains how they can be used to implement a “flat” (unsegmented) memory model or a segmented memory model.

Chapter 4 — Protection. Describes the support for page and segment protection provided in the IA-32 architecture. This chapter also explains the implementation of privilege rules, stack switching, pointer validation, user and supervisor modes.

Chapter 5 — Interrupt and Exception Handling. Describes the basic interrupt mechanisms defined in the IA-32 architecture, shows how interrupts and exceptions relate to protection, and describes how the architecture handles each exception type. Reference information for each IA-32 exception is given at the end of this chapter.

Chapter 6 — Task Management. Describes the mechanisms that the IA-32 architecture provides to support multitasking and inter-task protection.

Chapter 7 — Multiple Processor Management. Describes the instructions and flags that support multiple processors with shared memory, memory ordering, and the advanced programmable interrupt controller (APIC).

Chapter 8 — Processor Management and Initialization. Defines the state of an IA-32 processor after reset initialization. This chapter also explains how to set up an IA-32 processor for real-address mode operation and protected mode operation, and how to switch between modes.

Chapter 9 — Memory Cache Control. Describes the general concept of caching, the caching mechanisms supported by the IA-32 architecture, and the cache control instructions. This chapter also describes the memory type range registers (MTRRs) and how they can be used to map memory types of physical memory.

Chapter 10 — Intel MMX Technology System Programming. Describes those aspects of the Intel MMX technology that must be handled and considered at the system programming level, including task switching, exception handling, and compatibility with existing system environments.
Chapter 11 — SSE and SSE2 System Programming. Describes those aspects of SSE and SSE2 extensions that must be handled and considered at the system programming level, including task switching, exception handling, and compatibility with existing system environments.

Chapter 12 — System Management. Describes the IA-32 architecture’s system management mode (SMM) and the thermal monitoring facilities.

Chapter 13 — Machine-Check Architecture. Describes the machine-check architecture.

Chapter 14 — Debugging and Performance Monitoring. Describes the debugging registers and other debug mechanism provided in the IA-32 architecture. This chapter also describes the time-stamp counter and the performance-monitoring counters.

Chapter 15 — 8086 Emulation. Describes the real-address and virtual-8086 modes of the IA-32 architecture.

Chapter 16 — Mixing 16-Bit and 32-Bit Code. Describes how to mix 16-bit and 32-bit code modules within the same program or task.

Chapter 17 — IA-32 Architecture Compatibility. Describes the programming among the IA-32 processors, which include the Intel 286, Intel386™, Intel486™, Pentium, P6 family, and Pentium 4 processors. The P6 family includes the Pentium Pro, Pentium II, and Pentium III processors. The Pentium 4 processor is the first of a family of IA-32 processors based on the new Intel NetBurst micro-architecture. The differences among the 32-bit IA-32 processors are also described throughout the three volumes of the IA-32 Software Developer’s Manual, as relevant to particular features of the architecture. This chapter provides a collection of all the relevant compatibility information for all IA-32 processors and also describes the basic differences with respect to the 16-bit IA-32 processors (the Intel 8086 and Intel 286 processors).

Appendix A — Performance-Monitoring Events. Lists the events that can be counted with the performance-monitoring counters and the codes used to select these events.

Appendix B — Model Specific Registers (MSRs). Lists the MSRs available in the Pentium, P6 family, and Pentium 4 processors and their functions.

Appendix C — Dual-Processor (DP) Bootup Sequence Example (Specific to Pentium Processors). Gives an example of how to use the DP protocol to boot two Pentium processors (a primary processor and a secondary processor) in a DP system and initialize their APICs.

Appendix D — Multiple-Processor (MP) Bootup Sequence Example (Specific to P6 Family Processors). Gives an example of how to use of the MP protocol to boot two P6 family processors in a multiple-processor (MP) system and initialize their APICs.

Appendix E — Programming the LINT0 and LINT1 Inputs. Gives an example of how to program the LINT0 and LINT1 pins for specific interrupt vectors.

Appendix E — Interpreting Machine-Check Error Codes. Gives an example of how to interpret the error codes for a machine-check error that occurred on a P6 family processor.

Appendix F — APIC Bus Message Formats. Describes the message formats for messages transmitted on the APIC bus for P6 family and Pentium processors.
1.5. NOTATIONAL CONVENTIONS

This manual uses special notation for data-structure formats, for symbolic representation of instructions, and for hexadecimal numbers. A review of this notation makes the manual easier to read.

1.5.1. Bit and Byte Order

In illustrations of data structures in memory, smaller addresses appear toward the bottom of the figure; addresses increase toward the top. Bit positions are numbered from right to left. The numerical value of a set bit is equal to two raised to the power of the bit position. IA-32 processors are “little endian” machines; this means the bytes of a word are numbered starting from the least significant byte. Figure 1-1 illustrates these conventions.

![Bit and Byte Order Diagram]

**Figure 1-1. Bit and Byte Order**

1.5.2. Reserved Bits and Software Compatibility

In many register and memory layout descriptions, certain bits are marked as reserved. When bits are marked as reserved, it is essential for compatibility with future processors that software treat these bits as having a future, though unknown, effect. The behavior of reserved bits should be regarded as not only undefined, but unpredictable. Software should follow these guidelines in dealing with reserved bits:

- Do not depend on the states of any reserved bits when testing the values of registers which contain such bits. Mask out the reserved bits before testing.
- Do not depend on the states of any reserved bits when storing to memory or to a register.
- Do not depend on the ability to retain information written into any reserved bits.
- When loading a register, always load the reserved bits with the values indicated in the documentation, if any, or reload them with values previously read from the same register.
NOTE

Avoid any software dependence upon the state of reserved bits in IA-32 registers. Depending upon the values of reserved register bits will make software dependent upon the unspecified manner in which the processor handles these bits. Programs that depend upon reserved values risk incompatibility with future processors.

1.5.3. Instruction Operands

When instructions are represented symbolically, a subset of the IA-32 assembly language is used. In this subset, an instruction has the following format:

\[ label: \text{mnemonic} \ argument1, \ argument2, \ argument3 \]

where:

- A \textbf{label} is an identifier which is followed by a colon.
- A \textbf{mnemonic} is a reserved name for a class of instruction opcodes which have the same function.
- The operands \textit{argument1}, \textit{argument2}, and \textit{argument3} are optional. There may be from zero to three operands, depending on the opcode. When present, they take the form of either literals or identifiers for data items. Operand identifiers are either reserved names of registers or are assumed to be assigned to data items declared in another part of the program (which may not be shown in the example).

When two operands are present in an arithmetic or logical instruction, the right operand is the source and the left operand is the destination.

For example:

\texttt{LOADREG: MOV EAX, SUBTOTAL}

In this example, LOADREG is a label, MOV is the mnemonic identifier of an opcode, EAX is the destination operand, and SUBTOTAL is the source operand. Some assembly languages put the source and destination in reverse order.

1.5.4. Hexadecimal and Binary Numbers

Base 16 (hexadecimal) numbers are represented by a string of hexadecimal digits followed by the character H (for example, F82EH). A hexadecimal digit is a character from the following set: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, and F.
Base 2 (binary) numbers are represented by a string of 1s and 0s, sometimes followed by the character B (for example, 1010B). The “B” designation is only used in situations where confusion as to the type of number might arise.

1.5.5. Segmented Addressing

The processor uses byte addressing. This means memory is organized and accessed as a sequence of bytes. Whether one or more bytes are being accessed, a byte address is used to locate the byte or bytes in memory. The range of memory that can be addressed is called an address space.

The processor also supports segmented addressing. This is a form of addressing where a program may have many independent address spaces, called segments. For example, a program can keep its code (instructions) and stack in separate segments. Code addresses would always refer to the code space, and stack addresses would always refer to the stack space. The following notation is used to specify a byte address within a segment:

\textit{Segment-register:Byte-address}

For example, the following segment address identifies the byte at address FF79H in the segment pointed by the DS register:

\texttt{DS:FF79H}

The following segment address identifies an instruction address in the code segment. The CS register points to the code segment and the EIP register contains the address of the instruction.

\texttt{CS:EIP}

1.5.6. Exceptions

An exception is an event that typically occurs when an instruction causes an error. For example, an attempt to divide by zero generates an exception. However, some exceptions, such as breakpoints, occur under other conditions. Some types of exceptions may provide error codes. An error code reports additional information about the error. An example of the notation used to show an exception and error code is shown below.

\#PF(fault code)

This example refers to a page-fault exception under conditions where an error code naming a type of fault is reported. Under some conditions, exceptions which produce error codes may not be able to report an accurate code. In this case, the error code is zero, as shown below for a general-protection exception.

\#GP(0)

1.6. RELATED LITERATURE

Literature related to IA-32 processors is listed on-line at the following Intel web site:
http://developer.intel.com/design/processor/

Some of the documents listed at this web site can be viewed on-line; others can be ordered on-line. The literature available is listed by Intel processor and then by the following literature types: applications notes, data sheets, manuals, papers, and specification updates. The following literature may be of interest:

- Data Sheet for a particular Intel IA-32 processor.
- Specification Update for a particular Intel IA-32 processor.
- AP-485, Intel Processor Identification and the CPUID Instruction, Order Number 241618.
Instruction Format
This chapter describes the instruction format for all IA-32 processors.

### 2.1. GENERAL INSTRUCTION FORMAT

All IA-32 instruction encodings are subsets of the general instruction format shown in Figure 2-1. Instructions consist of optional instruction prefixes (in any order), one or two primary opcode bytes, an addressing-form specifier (if required) consisting of the ModR/M byte and sometimes the SIB (Scale-Index-Base) byte, a displacement (if required), and an immediate data field (if required).

<table>
<thead>
<tr>
<th>Instruction Prefixes</th>
<th>Opcode</th>
<th>ModR/M</th>
<th>SIB</th>
<th>Displacement</th>
<th>Immediate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Up to four prefixes of 1-byte each (optional)</td>
<td>1 or 2 byte opcode</td>
<td>1 byte (if required)</td>
<td>1 byte (if required)</td>
<td>Address displacement of 1, 2, or 4 bytes or none</td>
<td>Immediate data of 1, 2, or 4 bytes or none</td>
</tr>
</tbody>
</table>

![Figure 2-1. IA-32 Instruction Format](image)

### 2.2. INSTRUCTION PREFIXES

The instruction prefixes are divided into four groups, each with a set of allowable prefix codes:

- **Group 1**
  - Lock and repeat prefixes:
    - F0H—LOCK.
    - F2H—REPNE/REPNZ (used only with string instructions).
    - F3H—REP (use only with string instructions).
    - F3H—REPE/REPZ (use only with string instructions).

- **Group 2**
  - Segment override prefixes:
INSTRUCTION FORMAT

- 2EH—CS segment override (use with any branch instruction is reserved).
- 36H—SS segment override prefix (use with any branch instruction is reserved).
- 3EH—DS segment override prefix (use with any branch instruction is reserved).
- 26H—ES segment override prefix (use with any branch instruction is reserved).
- 64H—FS segment override prefix (use with any branch instruction is reserved).
- 65H—GS segment override prefix (use with any branch instruction is reserved).

Branch hints:
- 2EH—Branch not taken (used only with Jcc instructions).
- 3EH—Branch taken (used only with Jcc instructions).

Group 3
- 66H—Operand-size override prefix.

Group 4
- 67H—Address-size override prefix.

For each instruction, one prefix may be used from each of these groups and be placed in any order. The effect of redundant prefixes (more than one prefix from a group) is undefined and may vary from processor to processor.

The LOCK prefix forces an atomic operation to insure exclusive use of shared memory in a multiprocessor environment. See “LOCK—Assert LOCK# Signal Prefix” in Chapter 3, Instruction Set Reference, for a detailed description of this prefix and the instructions with which it can be used.

The repeat prefixes cause an instruction to be repeated for each element of a string. They can be used only with the string instructions: MOVS, CMPS, SCAS, LODS, and STOS. Use of the repeat prefixes with other IA-32 instructions is reserved and may cause unpredictable behavior.

The branch hint prefixes allow a program to give a hint to the processor about the most likely code path that will be taken at a branch. These prefixes can only be used with the conditional branch instructions (Jcc). These prefixes were introduced in the Pentium 4 processors as part of the SSE2 extensions.

The operand-size override prefix allows a program to switch between 16- and 32-bit operand sizes. Either operand size can be the default. This prefix selects the non-default size. This prefix has no effect on instructions that use 64-bit or 128-bit operands. Also, it should not be used as a prefix with SSE and SSE2 instructions (see the discussion below of the SSE and SSE2 opcode encodings).

The address-size override prefix allows a program to switch between 16- and 32-bit addressing. Either address size can be the default. This prefix selects the non-default size. This prefix is ignored when the operands for an instruction do not reside in memory.

Some of the SSE and SSE2 instructions have three-byte opcodes. For these three-byte opcodes, the third opcode byte is F3H for SSE instructions and F2H, F3H, or 66H for SSE2 instructions.
When one of these encodings in this group (F2H, F3H, or 66H) is used with a third opcode byte for an SSE or SSE2 instruction, the use of any of the other encoding in the group as a prefix is reserved. For example, the CVTDQ2PD instruction has the three-byte opcode F3 OF E6. With this opcode, the use of the encodings F2H and 66H as prefixes is reserved.

2.3. OPCODE

The primary opcode is either 1 or 2 bytes. An additional 3-bit opcode field is sometimes encoded in the ModR/M byte. Smaller encoding fields can be defined within the primary opcode. These fields define the direction of the operation, the size of displacements, the register encoding, condition codes, or sign extension. The encoding of fields in the opcode varies, depending on the class of operation.

2.4. MODR/M AND SIB BYTES

Most instructions that refer to an operand in memory have an addressing-form specifier byte (called the ModR/M byte) following the primary opcode. The ModR/M byte contains three fields of information:

- The mod field combines with the r/m field to form 32 possible values: eight registers and 24 addressing modes.
- The reg/opcode field specifies either a register number or three more bits of opcode information. The purpose of the reg/opcode field is specified in the primary opcode.
- The r/m field can specify a register as an operand or can be combined with the mod field to encode an addressing mode.

Certain encodings of the ModR/M byte require a second addressing byte, the SIB byte, to fully specify the addressing form. The base-plus-index and scale-plus-index forms of 32-bit addressing require the SIB byte. The SIB byte includes the following fields:

- The scale field specifies the scale factor.
- The index field specifies the register number of the index register.
- The base field specifies the register number of the base register.

See Section 2.6., “Addressing-Mode Encoding of ModR/M and SIB Bytes”, for the encodings of the ModR/M and SIB bytes.

2.5. DISPLACEMENT AND IMMEDIATE BYTES

Some addressing forms include a displacement immediately following either the ModR/M or SIB byte. If a displacement is required, it can be 1, 2, or 4 bytes.

If the instruction specifies an immediate operand, the operand always follows any displacement bytes. An immediate operand can be 1, 2 or 4 bytes.
2.6. ADDRESSING-MODE ENCODING OF MODR/M AND SIB BYTES

The values and the corresponding addressing forms of the ModR/M and SIB bytes are shown in Tables 2-1 through 2-3. The 16-bit addressing forms specified by the ModR/M byte are in Table 2-1, and the 32-bit addressing forms specified by the ModR/M byte are in Table 2-2. Table 2-3 shows the 32-bit addressing forms specified by the SIB byte.

In Tables 2-1 and 2-2, the first column (labeled “Effective Address”) lists 32 different effective addresses that can be assigned to one operand of an instruction by using the Mod and R/M fields of the ModR/M byte. The first 24 effective addresses give the different ways of specifying a memory location; the last eight (specified by the Mod field encoding 11B) give the ways of specifying the general-purpose, MMX, and XMM registers. Each of the register encodings list four possible registers. For example, the first register-encoding (selected by the R/M field encoding 000B) indicates the general-purpose registers EAX, AX or AL, MMX register MM0, or XMM register XMM0. Which of these five registers is used is determined by the opcode byte and the operand-size attribute, which select either the EAX register (32 bits) or AX register (16 bits).

The second and third columns in Tables 2-1 and 2-2 gives the binary encodings of the Mod and R/M fields in the ModR/M byte, respectively, required to obtain the associated effective address listed in the first column. All 32 possible combinations of the Mod and R/M fields are listed.

Across the top of Tables 2-1 and 2-2, the eight possible values of the 3-bit Reg/Opcode field are listed, in decimal (sixth row from top) and in binary (seventh row from top). The seventh row is labeled “REG=”, which represents the use of these 3 bits to give the location of a second operand, which must be a general-purpose, MMX, or XMM register. If the instruction does not require a second operand to be specified, then the 3 bits of the Reg/Opcode field may be used as an extension of the opcode, which is represented by the sixth row, labeled “/digit (Opcode)”. The five rows above give the byte, word, and doubleword general-purpose registers, the MMX registers, and the XMM registers that correspond to the register numbers, with the same assignments as for the R/M field when Mod field encoding is 11B. As with the R/M field register options, which of the five possible registers is used is determined by the opcode byte along with the operand-size attribute.

The body of Tables 2-1 and 2-2 (under the label “Value of ModR/M Byte (in Hexadecimal)”) contains a 32 by 8 array giving all of the 256 values of the ModR/M byte, in hexadecimal. Bits 3, 4 and 5 are specified by the column of the table in which a byte resides, and the row specifies bits 0, 1 and 2, and also bits 6 and 7.

**NOTES:**

1. The default segment register is SS for the effective addresses containing a BP index, DS for other effective addresses.
2. The “disp16” nomenclature denotes a 16-bit displacement following the ModR/M byte, to be added to the index.
3. The “disp8” nomenclature denotes an 8-bit displacement following the ModR/M byte, to be sign-extended and added to the index.

### NOTES:
1. The [-][-] nomenclature means a SI or follows the ModR/M byte.
2. The disp32 nomenclature denotes a 32-bit displacement following the SI or byte, to be added to the index.
3. The disp8 nomenclature denotes an 8-bit displacement following the SI or byte, to be sign-extended and added to the index.
Table 2-3 is organized similarly to Tables 2-1 and 2-2, except that its body gives the 256 possible values of the SIB byte, in hexadecimal. Which of the 8 general-purpose registers will be used as base is indicated across the top of the table, along with the corresponding values of the base field (bits 0, 1 and 2) in decimal and binary. The rows indicate which register is used as the index (determined by bits 3, 4 and 5) along with the scaling factor (determined by bits 6 and 7).

NOTE:
1. The [*] nomenclature means a disp32 with no base if MOD is 00, [EBP] otherwise. This provides the following addressing modes:

   disp32[index] (MOD=00).
   disp8[EBP][index](MOD=01).
   disp32[EBP][index](MOD=10).
Instruction Set Reference
This chapter describes the complete IA-32 instruction set, including the general-purpose, x87 FPU, MMX, SSE, SSE2, and system instructions. The instruction descriptions are arranged in alphabetical order. For each instruction, the forms are given for each operand combination, including the opcode, operands required, and a description. Also given for each instruction are a description of the instruction and its operands, an operational description, a description of the effect of the instructions on flags in the EFLAGS register, and a summary of the exceptions that can be generated.

3.1. INTERPRETING THE INSTRUCTION REFERENCE PAGES

This section describes the information contained in the various sections of the instruction reference pages that make up the majority of this chapter. It also explains the notational conventions and abbreviations used in these sections.

3.1.1. Instruction Format

The following is an example of the format used for each IA-32 instruction description in this chapter:

**CMC—Complement Carry Flag**

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F5</td>
<td>CMC</td>
<td>Complement carry flag</td>
</tr>
</tbody>
</table>

3.1.1.1. OPCODE COLUMN

The “Opcode” column gives the complete object code produced for each form of the instruction. When possible, the codes are given as hexadecimal bytes, in the same order in which they appear in memory. Definitions of entries other than hexadecimal bytes are as follows:

- **/digit**—A digit between 0 and 7 indicates that the ModR/M byte of the instruction uses only the r/m (register or memory) operand. The reg field contains the digit that provides an extension to the instruction's opcode.
- **/r**—Indicates that the ModR/M byte of the instruction contains both a register operand and an r/m operand.
INSTRUCTION SET REFERENCE

- **cb, cw, cd, cp**—A 1-byte (cb), 2-byte (cw), 4-byte (cd), or 6-byte (cp) value following the opcode that is used to specify a code offset and possibly a new value for the code segment register.

- **ib, iw, id**—A 1-byte (ib), 2-byte (iw), or 4-byte (id) immediate operand to the instruction that follows the opcode, ModR/M bytes or scale-indexing bytes. The opcode determines if the operand is a signed value. All words and doublewords are given with the low-order byte first.

- **+rb, +rw, +rd**—A register code, from 0 through 7, added to the hexadecimal byte given at the left of the plus sign to form a single opcode byte. The register codes are given in Table 3-3.

- **+i**—A number used in floating-point instructions when one of the operands is ST(i) from the FPU register stack. The number i (which can range from 0 to 7) is added to the hexadecimal byte given at the left of the plus sign to form a single opcode byte.

### Table 3-1. Register Encodings Associated with the +rb, +rw, and +rd Nomenclature

3.1.1.2. INSTRUCTION COLUMN

The “Instruction” column gives the syntax of the instruction statement as it would appear in an ASM386 program. The following is a list of the symbols used to represent operands in the instruction statements:

- **rel8**—A relative address in the range from 128 bytes before the end of the instruction to 127 bytes after the end of the instruction.

- **rel16 and rel32**—A relative address within the same code segment as the instruction assembled. The rel16 symbol applies to instructions with an operand-size attribute of 16 bits; the rel32 symbol applies to instructions with an operand-size attribute of 32 bits.

- **ptr16:16 and ptr16:32**—A far pointer, typically in a code segment different from that of the instruction. The notation 16:16 indicates that the value of the pointer has two parts. The value to the left of the colon is a 16-bit selector or value destined for the code segment register. The value to the right corresponds to the offset within the destination segment.
The ptr16:16 symbol is used when the instruction's operand-size attribute is 16 bits; the ptr16:32 symbol is used when the operand-size attribute is 32 bits.

- **r8**—One of the byte general-purpose registers AL, CL, DL, BL, AH, CH, DH, or BH.
- **r16**—One of the word general-purpose registers AX, CX, DX, BX, SP, BP, SI, or DI.
- **r32**—One of the doubleword general-purpose registers EAX, ECX, EDX, EBX, ESP, EBP, ESI, or EDI.
- **imm8**—An immediate byte value. The imm8 symbol is a signed number between −128 and +127 inclusive. For instructions in which imm8 is combined with a word or doubleword operand, the immediate value is sign-extended to form a word or doubleword. The upper byte of the word is filled with the topmost bit of the immediate value.
- **imm16**—An immediate word value used for instructions whose operand-size attribute is 16 bits. This is a number between −32,768 and +32,767 inclusive.
- **imm32**—An immediate doubleword value used for instructions whose operand-size attribute is 32 bits. It allows the use of a number between +2,147,483,647 and −2,147,483,648 inclusive.
- **r/m8**—A byte operand that is either the contents of a byte general-purpose register (AL, BL, CL, DL, AH, BH, CH, and DH), or a byte from memory.
- **r/m16**—A word general-purpose register or memory operand used for instructions whose operand-size attribute is 16 bits. The word general-purpose registers are: AX, BX, CX, DX, SP, BP, SI, and DI. The contents of memory are found at the address provided by the effective address computation.
- **r/m32**—A doubleword general-purpose register or memory operand used for instructions whose operand-size attribute is 32 bits. The doubleword general-purpose registers are: EAX, EBX, ECX, EDX, ESP, EBP, ESI, and EDI. The contents of memory are found at the address provided by the effective address computation.
- **m**—A 16- or 32-bit operand in memory.
- **m8**—A byte operand in memory, usually expressed as a variable or array name, but pointed to by the DS:(E)SI or ES:(E)DI registers. This nomenclature is used only with the string instructions and the XLAT instruction.
- **m16**—A word operand in memory, usually expressed as a variable or array name, but pointed to by the DS:(E)SI or ES:(E)DI registers. This nomenclature is used only with the string instructions.
- **m32**—A doubleword operand in memory, usually expressed as a variable or array name, but pointed to by the DS:(E)SI or ES:(E)DI registers. This nomenclature is used only with the string instructions.
- **m64**—A memory quadword operand in memory. This nomenclature is used only with the CMPXCHG8B instruction.
- **m128**—A memory double quadword operand in memory. This nomenclature is used only with the SSE and SSE2 instructions.
• **m16:16, m16:32**—A memory operand containing a far pointer composed of two numbers. The number to the left of the colon corresponds to the pointer's segment selector. The number to the right corresponds to its offset.

• **m16&32, m16&16, m32&32**—A memory operand consisting of data item pairs whose sizes are indicated on the left and the right side of the ampersand. All memory addressing modes are allowed. The m16&16 and m32&32 operands are used by the BOUND instruction to provide an operand containing an upper and lower bounds for array indices. The m16&32 operand is used by LIDT and LGDT to provide a word with which to load the limit field, and a doubleword with which to load the base field of the corresponding GDTR and IDTR registers.

• **moffs8, moffs16, moffs32**—A simple memory variable (memory offset) of type byte, word, or doubleword used by some variants of the MOV instruction. The actual address is given by a simple offset relative to the segment base. No ModR/M byte is used in the instruction. The number shown with moffs indicates its size, which is determined by the address-size attribute of the instruction.

• **Sreg**—A segment register. The segment register bit assignments are ES=0, CS=1, SS=2, DS=3, FS=4, and GS=5.

• **m32fp, m64fp, m80fp**—A single-precision, double-precision, and double extended-precision (respectively) floating-point operand in memory. These symbols designate floating-point values that are used as operands for x87 FPU floating-point instructions.

• **m16int, m32int, m64int**—A word, doubleword, and quadword integer (respectively) operand in memory. These symbols designate integers that are used as operands for x87 FPU integer instructions.

• **ST or ST(0)**—The top element of the FPU register stack.

• **ST(i)**—The \( i \)th element from the top of the FPU register stack. \( (i \leftarrow 0 \text{ through } 7) \)

• **mm**—An MMX register. The 64-bit MMX registers are: MM0 through MM7.

• **mm/m32**—The low order 32 bits of an MMX register or a 32-bit memory operand. The 64-bit MMX registers are: MM0 through MM7. The contents of memory are found at the address provided by the effective address computation.

• **mm/m64**—An MMX register or a 64-bit memory operand. The 64-bit MMX registers are: MM0 through MM7. The contents of memory are found at the address provided by the effective address computation.

• **xmm**—An XMM register. The 128-bit XMM registers are: XMM0 through XMM7.

• **xmm/m32**—An XMM register or a 32-bit memory operand. The 128-bit XMM registers are XMM0 through XMM7. The contents of memory are found at the address provided by the effective address computation.

• **xmm/m64**—An XMM register or a 64-bit memory operand. The 128-bit SIMD floating-point registers are XMM0 through XMM7. The contents of memory are found at the address provided by the effective address computation.
• **xmm/m128**—An XMM register or a 128-bit memory operand. The 128-bit XMM registers are XMM0 through XMM7. The contents of memory are found at the address provided by the effective address computation.

### 3.1.1.3. DESCRIPTION COLUMN

The “Description” column following the “Instruction” column briefly explains the various forms of the instruction. The following “Description” and “Operation” sections contain more details of the instruction’s operation.

### 3.1.1.4. DESCRIPTION

The “Description” section describes the purpose of the instructions and the required operands. It also discusses the effect of the instruction on flags.

### 3.1.2. Operation

The “Operation” section contains an algorithmic description (written in pseudo-code) of the instruction. The pseudo-code uses a notation similar to the Algol or Pascal language. The algorithms are composed of the following elements:

- Comments are enclosed within the symbol pairs “(*” and “*)”.
- Compound statements are enclosed in keywords, such as IF, THEN, ELSE, and FI for an if statement, DO and OD for a do statement, or CASE ... OF and ESAC for a case statement.
- A register name implies the contents of the register. A register name enclosed in brackets implies the contents of the location whose address is contained in that register. For example, ES:[DI] indicates the contents of the location whose ES segment relative address is in register DI. [SI] indicates the contents of the address contained in register SI relative to the SI register’s default segment (DS) or overridden segment.
- Parentheses around the “E” in a general-purpose register name, such as (E)SI, indicates that an offset is read from the SI register if the current address-size attribute is 16 or is read from the ESI register if the address-size attribute is 32.
- Brackets are also used for memory operands, where they mean that the contents of the memory location is a segment-relative offset. For example, [SRC] indicates that the contents of the source operand is a segment-relative offset.
- A ← B; indicates that the value of B is assigned to A.
- The symbols =, ≠, ≥, and ≤ are relational operators used to compare two values, meaning equal, not equal, greater or equal, less or equal, respectively. A relational expression such as A ← B is TRUE if the value of A is equal to B; otherwise it is FALSE.
- The expression “≪ COUNT” and “≫ COUNT” indicates that the destination operand should be shifted left or right, respectively, by the number of bits indicated by the count operand.
The following identifiers are used in the algorithmic descriptions:

- **OperandSize and AddressSize**—The OperandSize identifier represents the operand-size attribute of the instruction, which is either 16 or 32 bits. The AddressSize identifier represents the address-size attribute, which is either 16 or 32 bits. For example, the following pseudo-code indicates that the operand-size attribute depends on the form of the CMPS instruction used.

  IF instruction ← CMPSW
  THEN OperandSize ← 16;
  ELSE
      IF instruction ← CMPSD
      THEN OperandSize ← 32;
      FI;
  FI;

  See “Operand-Size and Address-Size Attributes” in Chapter 3 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for general guidelines on how these attributes are determined.

- **StackAddrSize**—Represents the stack address-size attribute associated with the instruction, which has a value of 16 or 32 bits (see “Address-Size Attribute for Stack” in Chapter 6 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*).

- **SRC**—Represents the source operand.

- **DEST**—Represents the destination operand.

The following functions are used in the algorithmic descriptions:

- **ZeroExtend(value)**—Returns a value zero-extended to the operand-size attribute of the instruction. For example, if the operand-size attribute is 32, zero extending a byte value of –10 converts the byte from F6H to a doubleword value of 000000F6H. If the value passed to the ZeroExtend function and the operand-size attribute are the same size, ZeroExtend returns the value unaltered.

- **SignExtend(value)**—Returns a value sign-extended to the operand-size attribute of the instruction. For example, if the operand-size attribute is 32, sign extending a byte containing the value –10 converts the byte from F6H to a doubleword value of FFFFFFF6H. If the value passed to the SignExtend function and the operand-size attribute are the same size, SignExtend returns the value unaltered.

- **SaturateSignedWordToSignedByte**—Converts a signed 16-bit value to a signed 8-bit value. If the signed 16-bit value is less than –128, it is represented by the saturated value –128 (80H); if it is greater than 127, it is represented by the saturated value 127 (7FH).

- **SaturateSignedDwordToSignedWord**—Converts a signed 32-bit value to a signed 16-bit value. If the signed 32-bit value is less than –32768, it is represented by the saturated value –32768 (8000H); if it is greater than 32767, it is represented by the saturated value 32767 (7FFFH).

- **SaturateSignedWordToUnsignedByte**—Converts a signed 16-bit value to an unsigned 8-bit value. If the signed 16-bit value is less than zero, it is represented by the saturated
value zero (00H); if it is greater than 255, it is represented by the saturated value 255 (FFH).

- **SaturateToSignedByte**—Represents the result of an operation as a signed 8-bit value. If the result is less than –128, it is represented by the saturated value –128 (80H); if it is greater than 127, it is represented by the saturated value 127 (7FH).

- **SaturateToSignedWord**—Represents the result of an operation as a signed 16-bit value. If the result is less than –32768, it is represented by the saturated value –32768 (8000H); if it is greater than 32767, it is represented by the saturated value 32767 (7FFFH).

- **SaturateToUnsignedByte**—Represents the result of an operation as a signed 8-bit value. If the result is less than zero it is represented by the saturated value zero (00H); if it is greater than 255, it is represented by the saturated value 255 (FFH).

- **SaturateToUnsignedWord**—Represents the result of an operation as a signed 16-bit value. If the result is less than zero it is represented by the saturated value zero (00H); if it is greater than 65535, it is represented by the saturated value 65535 (FFFFH).

- **LowOrderWord**(DEST * SRC)—Multiplies a word operand by a word operand and stores the least significant word of the doubleword result in the destination operand.

- **HighOrderWord**(DEST * SRC)—Multiplies a word operand by a word operand and stores the most significant word of the doubleword result in the destination operand.

- **Push**(value)—Pushes a value onto the stack. The number of bytes pushed is determined by the operand-size attribute of the instruction. See the “Operation” section in “PUSH—Push Word or Doubleword Onto the Stack” in this chapter for more information on the push operation.

- **Pop()** removes the value from the top of the stack and returns it. The statement EAX ← Pop(); assigns to EAX the 32-bit value from the top of the stack. Pop will return either a word or a doubleword depending on the operand-size attribute. See the “Operation” section in Chapter 3, “POP—Pop a Value from the Stack” for more information on the pop operation.

- **PopRegisterStack**—Marks the FPU ST(0) register as empty and increments the FPU register stack pointer (TOP) by 1.

- **Switch-Tasks**—Performs a task switch.

- **Bit**(BitBase, BitOffset)—Returns the value of a bit within a bit string, which is a sequence of bits in memory or a register. Bits are numbered from low-order to high-order within registers and within memory bytes. If the base operand is a register, the offset can be in the range 0..31. This offset addresses a bit within the indicated register. An example, the function Bit[EAX, 21] is illustrated in Figure 3-1.
3.1.3. Intel C/C++ Compiler Intrinsics Equivalents

The Intel C/C++ compiler intrinsics equivalents are special C/C++ coding extensions that allow using the syntax of C function calls and C variables instead of hardware registers. Using these intrinsics frees programmers from having to manage registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that executables runs faster.

The following sections discuss the intrinsics API and the MMX technology and SIMD floating-point intrinsics. Each intrinsic equivalent is listed with the instruction description. There may be additional intrinsics that do not have an instruction equivalent. It is strongly recommended that the reader reference the compiler documentation for the complete list of supported intrinsics. Please refer to the Intel C/C++ Compiler User’s Guide With Support for the Streaming SIMD Extensions 2 (Order Number 718195-2001). See Appendix C, Intel C/C++ Compiler Intrinsics and Functional Equivalents for more information on using intrinsics.

3.1.3.1. THE INTRINSICS API

The benefit of coding with MMX technology intrinsics and the SSE and SSE2 intrinsics is that you can use the syntax of C function calls and C variables instead of hardware registers. This frees you from managing registers and programming assembly. Further, the compiler optimizes the instruction scheduling so that your executable runs faster. For each computational and data manipulation instruction in the new instruction set, there is a corresponding C intrinsic that implements it directly. The intrinsics allow you to specify the underlying implementation (instruction selection) of an algorithm yet leave instruction scheduling and register allocation to the compiler.

3.1.3.2. MMX TECHNOLOGY INTRINSICS

The MMX technology intrinsics are based on a new __m64 data type to represent the specific contents of an MMX technology register. You can specify values in bytes, short integers, 32-bit
values, or a 64-bit object. The __m64 data type, however, is not a basic ANSI C data type, and therefore you must observe the following usage restrictions:

- Use __m64 data only on the left-hand side of an assignment, as a return value, or as a parameter. You cannot use it with other arithmetic expressions (“+”, “>>”, and so on).
- Use __m64 objects in aggregates, such as unions to access the byte elements and structures; the address of an __m64 object may be taken.
- Use __m64 data only with the MMX technology intrinsics described in this guide and the Intel C/C++ Compiler User's Guide With Support for the Streaming SIMD Extensions 2 (Order Number 718195-2001). Refer to Appendix C, Intel C/C++ Compiler Intrinsics and Functional Equivalents for more information on using intrinsics.

### 3.1.3.3. SSE AND SSE2 INTRINSICS

The SSE and SSE2 intrinsics all make use of the XMM registers of the Pentium III and Pentium 4 Processors. There are three data types supported by these intrinsics: __m128, __m128d, and __m128i.

- The __m128 data type is used to represent the contents of an XMM register used by an SSE intrinsic. This is either four packed single-precision floating-point values or a scalar single-precision floating-point value.
- The __m128d data type holds two packed double-precision floating-point values or a scalar double-precision floating-point value.
- The __m128i data type can hold sixteen byte, eight word, or four doubleword, or two quadword integer values.

The compiler aligns __m128, __m128d, and __m128i local and global data to 16-byte boundaries on the stack. To align integer, float, or double arrays, you can use thedeclspec statement as described in the Intel C/C++ Compiler User's Guide With Support for the Streaming SIMD Extensions 2 (Order Number 718195-2001).

The __m128, __m128d, and __m128i data types are not basic ANSI C data types and therefore some restrictions are placed on their usage:

- Use __m128, __m128d, and __m128i only on the left-hand side of an assignment, as a return value, or as a parameter. Do not use it in other arithmetic expressions such as “+” and “>>”.
- Do not initialize __m128, __m128d, and __m128i with literals; there is no way to express 128-bit constants.
- Use __m128, __m128d, and __m128i objects in aggregates, such as unions (for example, to access the float elements) and structures. The address of these objects may be taken.
- Use __m128, __m128d, and __m128i data only with the intrinsics described in this user’s guide. Refer to Appendix C, Intel C/C++ Compiler Intrinsics and Functional Equivalents for more information on using intrinsics.
The compiler aligns __m128, __m128d, and __m128i local data to 16-byte boundaries on the stack. Global __m128 data is also aligned on 16-byte boundaries. (To align float arrays, you can use the alignment declspec described in the following section.) Because the new instruction set treats the SIMD floating-point registers in the same way whether you are using packed or scalar data, there is no __m32 data type to represent scalar data as you might expect. For scalar operations, you should use the __m128 objects and the “scalar” forms of the intrinsics; the compiler and the processor implement these operations with 32-bit memory references.

The suffixes ps and ss are used to denote “packed single” and “scalar single” precision operations. The packed floats are represented in right-to-left order, with the lowest word (right-most) being used for scalar operations: [z, y, x, w]. To explain how memory storage reflects this, consider the following example.

The operation

\[ float a[4] \leftarrow \{ 1.0, 2.0, 3.0, 4.0 \}; \]
\[ __m128 t \leftarrow _mm_load_ps(a); \]

produces the same result as follows:

\[ __m128 t \leftarrow _mm_set_ps(4.0, 3.0, 2.0, 1.0); \]

In other words,

\[ t \leftarrow [ 4.0, 3.0, 2.0, 1.0 ] \]

where the “scalar” element is 1.0.

Some intrinsics are “composites” because they require more than one instruction to implement them. You should be familiar with the hardware features provided by the SSE, SSE2, and MMX technology when writing programs with the intrinsics.

Keep the following three important issues in mind:

- Certain intrinsics, such as _mm_loadr_ps and _mm_cmpgt_ss, are not directly supported by the instruction set. While these intrinsics are convenient programming aids, be mindful of their implementation cost.
- Data loaded or stored as __m128 objects must generally be 16-byte-aligned.
- Some intrinsics require that their argument be immediates, that is, constant integers (literals), due to the nature of the instruction.
- The result of arithmetic operations acting on two NaN (Not a Number) arguments is undefined. Therefore, floating-point operations using NaN arguments will not match the expected behavior of the corresponding assembly instructions.

3.1.4. Flags Affected

The “Flags Affected” section lists the flags in the EFLAGS register that are affected by the instruction. When a flag is cleared, it is equal to 0; when it is set, it is equal to 1. The arithmetic and logical instructions usually assign values to the status flags in a uniform manner (see Appendix A, EFLAGS Cross-Reference, in the IA-32 Intel Architecture Software Developer's Manual, Volume 1). Non-conventional assignments are described in the “Operation” section. The values of flags listed as undefined may be changed by the instruction in an indeterminate manner. Flags that are not listed are unchanged by the instruction.

3.1.5. FPU Flags Affected

The floating-point instructions have an “FPU Flags Affected” section that describes how each instruction can affect the four condition code flags of the FPU status word.

3.1.6. Protected Mode Exceptions

The “Protected Mode Exceptions” section lists the exceptions that can occur when the instruction is executed in protected mode and the reasons for the exceptions. Each exception is given a mnemonic that consists of a pound sign (#) followed by two letters and an optional error code in parentheses. For example, #GP(0) denotes a general protection exception with an error code of 0. Table 3-2 associates each two-letter mnemonic with the corresponding interrupt vector number and exception name. See Chapter 5, Interrupt and Exception Handling, in the IA-32 Intel Architecture Software Developer's Manual, Volume 3, for a detailed description of the exceptions.

Application programmers should consult the documentation provided with their operating systems to determine the actions taken when exceptions occur.

### 3.1.7. Real-Address Mode Exceptions

The “Real-Address Mode Exceptions” section lists the exceptions that can occur when the instruction is executed in real-address mode (see Table 3-2).
3.1.8. Virtual-8086 Mode Exceptions

The “Virtual-8086 Mode Exceptions” section lists the exceptions that can occur when the instruction is executed in virtual-8086 mode (see Table 3-2).

3.1.9. Floating-Point Exceptions

The “Floating-Point Exceptions” section lists exceptions that can occur when an x87 FPU floating-point instruction is executed. All of these exception conditions result in a floating-point error exception (#MF, vector number 16) being generated. Table 3-3 associates a one- or two-letter mnemonic with the corresponding exception name. See “Floating-Point Exception Conditions” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a detailed description of these exceptions.

3.1.10. SIMD Floating-Point Exceptions

The “SIMD Floating-Point Exceptions” section lists exceptions that can occur when an SSE and SSE2 floating-point instruction is executed. All of these exception conditions result in a SIMD floating-point error exception (#XF, vector number 19) being generated. Table 3-4 associates a one-letter mnemonic with the corresponding exception name. For a detailed description of these exceptions, refer to “SSE and SSE2 Exceptions”, in Chapter 11 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1.
3.2. **INSTRUCTION REFERENCE**

The remainder of this chapter provides detailed descriptions of each of the IA-32 instructions.

AAA—ASCII Adjust After Addition

Description
Adjusts the sum of two unpacked BCD values to create an unpacked BCD result. The AL register is the implied source and destination operand for this instruction. The AAA instruction is only useful when it follows an ADD instruction that adds (binary addition) two unpacked BCD values and stores a byte result in the AL register. The AAA instruction then adjusts the contents of the AL register to contain the correct 1-digit unpacked BCD result.

If the addition produces a decimal carry, the AH register is incremented by 1, and the CF and AF flags are set. If there was no decimal carry, the CF and AF flags are cleared and the AH register is unchanged. In either case, bits 4 through 7 of the AL register are cleared to 0.

Operation
\[
\begin{align*}
&\text{IF } ((\text{AL AND } 0FH) > 9) \text{ OR } (\text{AF} \leftarrow 1) \\
&\quad \text{THEN} \\
&\quad \quad \text{AL} \leftarrow (\text{AL} + 6); \\
&\quad \quad \text{AH} \leftarrow \text{AH} + 1; \\
&\quad \quad \text{AF} \leftarrow 1; \\
&\quad \quad \text{CF} \leftarrow 1; \\
&\quad \text{ELSE} \\
&\quad \quad \text{AF} \leftarrow 0; \\
&\quad \quad \text{CF} \leftarrow 0; \\
&\quad \text{FI;} \\
&\text{AL} \leftarrow \text{AL AND } 0FH;
\end{align*}
\]

Flags Affected
The AF and CF flags are set to 1 if the adjustment results in a decimal carry; otherwise they are cleared to 0. The OF, SF, ZF, and PF flags are undefined.

Exceptions (All Operating Modes)
None.
AAD—ASCII Adjust AX Before Division

Description
Adjusts two unpacked BCD digits (the least-significant digit in the AL register and the most-significant digit in the AH register) so that a division operation performed on the result will yield a correct unpacked BCD value. The AAD instruction is only useful when it precedes a DIV instruction that divides (binary division) the adjusted value in the AX register by an unpacked BCD value.

The AAD instruction sets the value in the AL register to \((AL + (10 \times AH))\), and then clears the AH register to 00H. The value in the AX register is then equal to the binary equivalent of the original unpacked two-digit (base 10) number in registers AH and AL.

The generalized version of this instruction allows adjustment of two unpacked digits of any number base (see the “Operation” section below), by setting the \(imm8\) byte to the selected number base (for example, 08H for octal, 0AH for decimal, or 0CH for base 12 numbers). The AAD mnemonic is interpreted by all assemblers to mean adjust ASCII (base 10) values. To adjust values in another number base, the instruction must be hand coded in machine code (D5 \(imm8\)).

Operation
\[
\begin{align*}
\text{tempAL} & \leftarrow AL; \\
\text{tempAH} & \leftarrow AH; \\
\text{AL} & \leftarrow (\text{tempAL} + (\text{tempAH} \times imm8)) \text{ AND FFH}; \quad (* \text{ imm8 is set to 0AH for the AAD mnemonic } *) \\
\text{AH} & \leftarrow 0
\end{align*}
\]

The immediate value \((imm8)\) is taken from the second byte of the instruction.

Flags Affected
The SF, ZF, and PF flags are set according to the resulting binary value in the AL register; the OF, AF, and CF flags are undefined.

Exceptions (All Operating Modes)
None.
AAM—ASCII Adjust AX After Multiply

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D4 0A</td>
<td>AAM</td>
<td>ASCII adjust AX after multiply</td>
</tr>
<tr>
<td>D4 ib</td>
<td>(No mnemonic)</td>
<td>Adjust AX after multiply to number base imm8</td>
</tr>
</tbody>
</table>

**Description**

Adjusts the result of the multiplication of two unpacked BCD values to create a pair of unpacked (base 10) BCD values. The AX register is the implied source and destination operand for this instruction. The AAM instruction is only useful when it follows an MUL instruction that multiplies (binary multiplication) two unpacked BCD values and stores a word result in the AX register. The AAM instruction then adjusts the contents of the AX register to contain the correct 2-digit unpacked (base 10) BCD result.

The generalized version of this instruction allows adjustment of the contents of the AX to create two unpacked digits of any number base (see the “Operation” section below). Here, the imm8 byte is set to the selected number base (for example, 08H for octal, 0AH for decimal, or 0CH for base 12 numbers). The AAM mnemonic is interpreted by all assemblers to mean adjust to ASCII (base 10) values. To adjust to values in another number base, the instruction must be hand coded in machine code (D4 imm8).

**Operation**

\[
\begin{align*}
\text{tempAL} & \leftarrow \text{AL}; \\
\text{AH} & \leftarrow \text{tempAL} / \text{imm8}; \; (\ast \text{imm8 is set to 0AH for the AAD mnemonic}) \\
\text{AL} & \leftarrow \text{tempAL} \text{MOD imm8}; \\
\end{align*}
\]

The immediate value (imm8) is taken from the second byte of the instruction.

**Flags Affected**

The SF, ZF, and PF flags are set according to the resulting binary value in the AL register. The OF, AF, and CF flags are undefined.

**Exceptions (All Operating Modes)**

None with the default immediate value of 0AH. If, however, an immediate value of 0 is used, it will cause a #DE (divide error) exception.
AAS—ASCII Adjust AL After Subtraction

Description
Adjusts the result of the subtraction of two unpacked BCD values to create a unpacked BCD result. The AL register is the implied source and destination operand for this instruction. The AAS instruction is only useful when it follows a SUB instruction that subtracts (binary subtraction) one unpacked BCD value from another and stores a byte result in the AL register. The AAA instruction then adjusts the contents of the AL register to contain the correct 1-digit unpacked BCD result.

If the subtraction produced a decimal carry, the AH register is decremented by 1, and the CF and AF flags are set. If no decimal carry occurred, the CF and AF flags are cleared, and the AH register is unchanged. In either case, the AL register is left with its top nibble set to 0.

Operation
IF ((AL AND 0FH) > 9) OR (AF ← 1)
THEN
    AL ← AL – 6;
    AH ← AH – 1;
    AF ← 1;
    CF ← 1;
ELSE
    CF ← 0;
    AF ← 0;
FI;
AL ← AL AND 0FH;

Flags Affected
The AF and CF flags are set to 1 if there is a decimal borrow; otherwise, they are cleared to 0. The OF, SF, ZF, and PF flags are undefined.

Exceptions (All Operating Modes)
None.
ADC—Add with Carry

Description

Adds the destination operand (first operand), the source operand (second operand), and the carry (CF) flag and stores the result in the destination operand. The destination operand can be a register or a memory location; the source operand can be an immediate, a register, or a memory location. (However, two memory operands cannot be used in one instruction.) The state of the CF flag represents a carry from a previous addition. When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.

The ADC instruction does not distinguish between signed or unsigned operands. Instead, the processor evaluates the result for both data types and sets the OF and CF flags to indicate a carry in the signed or unsigned result, respectively. The SF flag indicates the sign of the signed result.

The ADC instruction is usually executed as part of a multibyte or multiword addition in which an ADD instruction is followed by an ADC instruction.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation

DEST ← DEST + SRC + CF;

Flags Affected

The OF, SF, ZF, AF, CF, and PF flags are set according to the result.
ADC—Add with Carry (Continued)

Protected Mode Exceptions

#GP(0) If the destination is located in a non-writable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
**ADD—Add**

**Description**

Adds the first operand (destination operand) and the second operand (source operand) and stores the result in the destination operand. The destination operand can be a register or a memory location; the source operand can be an immediate, a register, or a memory location. (However, two memory operands cannot be used in one instruction.) When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.

The ADD instruction performs integer addition. It evaluates the result for both signed and unsigned integer operands and sets the OF and CF flags to indicate a carry (overflow) in the signed or unsigned result, respectively. The SF flag indicates the sign of the signed result.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

**Operation**

\[
\text{DEST} \leftarrow \text{DEST} + \text{SRC};
\]

**Flags Affected**

The OF, SF, ZF, AF, CF, and PF flags are set according to the result.
ADD—Add (Continued)

Protected Mode Exceptions

#GP(0) If the destination is located in a non-writable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains
a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
made.
ADDPD—Add Packed Double-Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 58</td>
<td>ADDPD xmm1, xmm2/m128</td>
<td>Add packed double-precision floating-point values from xmm2/m128 to xmm1.</td>
</tr>
</tbody>
</table>

Description

Performs a SIMD add of the two packed double-precision floating-point values from the source operand (second operand) and the destination operand (first operand), and stores the packed double-precision floating-point results in the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 11-3 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a SIMD double-precision floating-point operation.

Operation

DEST[63-0] ← DEST[63-0] + SRC[63-0];
DEST[127-64] ← DEST[127-64] + SRC[127-64];

Intel C/C++ Compiler Intrinsic Equivalent

ADDPD __m128d _mm_add_pd (m128d a, m128d b)

SIMD Floating-Point Exceptions

Overflow, Underflow, Invalid, Precision, Denormal.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
If memory operand is not aligned on a 16-byte boundary, regardless of segment.

#SS(0) For an illegal address in the SS segment.

#PF(fault-code) For a page fault.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
INSTRUCTION SET REFERENCE

ADDPD—Add Packed Double-Precision Floating-Point Values

(Continued)

If CPUID feature flag SSE2 is 0.

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.
Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.
#NM If TS in CR0 is set.
#XM If an unmasked SIMD floating-point exception and OSXMEXCPT in CR4 is 1.
#UD If an unmasked SIMD floating-point exception and OSXMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE2 is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault
ADDPS—Add Packed Single-Precision Floating-Point Values

**Description**
Performs a SIMD add of the four packed single-precision floating-point values from the source operand (second operand) and the destination operand (first operand), and stores the packed single-precision floating-point results in the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 10-5 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume I* for an illustration of a SIMD single-precision floating-point operation.

**Operation**
\[
\begin{align*}
\text{DEST}[31-0] & \leftarrow \text{DEST}[31-0] + \text{SRC}[31-0]; \\
\text{DEST}[63-32] & \leftarrow \text{DEST}[63-32] + \text{SRC}[63-32]; \\
\text{DEST}[95-64] & \leftarrow \text{DEST}[95-64] + \text{SRC}[95-64]; \\
\text{DEST}[127-96] & \leftarrow \text{DEST}[127-96] + \text{SRC}[127-96];
\end{align*}
\]

**Intel C/C++ Compiler Intrinsic Equivalent**
```
ADDPS _m128 _mm_add_ps(_m128 a, _m128 b)
```

**SIMD Floating-Point Exceptions**
Overflow, Underflow, Invalid, Precision, Denormal.

**Protected Mode Exceptions**
- **#GP(0)** For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
  
  If memory operand is not aligned on a 16-byte boundary, regardless of segment.
- **#SS(0)** For an illegal address in the SS segment.
- **#PF(fault-code)** For a page fault.
- **#NM** If TS in CR0 is set.
- **#XM** If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
- **#UD** If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
ADDPS—Add Packed Single-Precision Floating-Point Values (Continued)

If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.
Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.
#NM If TS in CR0 is set.
#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
ADDSD—Add Scalar Double-Precision Floating-Point Values

Description

Adds the low double-precision floating-point values from the source operand (second operand) and the destination operand (first operand), and stores the double-precision floating-point result in the destination operand. The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. The high quadword of the destination operand remains unchanged. See Figure 11-4 in the IA-32 Intel Architecture Software Developer’s Manual, Volume I for an illustration of a scalar double-precision floating-point operation.

Operation

DEST[63-0] ← DEST[63-0] + SRC[63-0];
* DEST[127-64] remains unchanged *;

Intel C/C++ Compiler Intrinsic Equivalent

ADDSD __m128d _mm_add_sd (m128d a, m128d b)

SIMD Floating-Point Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
ADDSS—Add Scalar Single-Precision Floating-Point Values

**Description**

Adds the low single-precision floating-point values from the source operand (second operand) and the destination operand (first operand), and stores the single-precision floating-point result in the destination operand. The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The three high-order doublewords of the destination operand remain unchanged. See Figure 10-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a scalar single-precision floating-point operation.

**Operation**

\[
\text{DEST}[31-0] \leftarrow \text{DEST}[31-0] + \text{SRC}[31-0];
\]

* DEST[127-32] remain unchanged *

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) If alignment checking is enabled and an unaligned memory reference is
made.
AND—Logical AND

**Description**

Performs a bitwise AND operation on the destination (first) and source (second) operands and stores the result in the destination operand location. The source operand can be an immediate, a register, or a memory location; the destination operand can be a register or a memory location. (However, two memory operands cannot be used in one instruction.) Each bit of the result is set to 1 if both corresponding bits of the first and second operands are 1; otherwise, it is set to 0.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

**Operation**

DEST ← DEST AND SRC;

**Flags Affected**

The OF and CF flags are cleared; the SF, ZF, and PF flags are set according to the result. The state of the AF flag is undefined.

**Protected Mode Exceptions**

#GP(0) If the destination operand points to a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.
AND—Logical AND (Continued)

#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
ARPL—Adjust RPL Field of Segment Selector

**Description**

Compares the RPL fields of two segment selectors. The first operand (the destination operand) contains one segment selector and the second operand (source operand) contains the other. (The RPL field is located in bits 0 and 1 of each operand.) If the RPL field of the destination operand is less than the RPL field of the source operand, the ZF flag is set and the RPL field of the destination operand is increased to match that of the source operand. Otherwise, the ZF flag is cleared and no change is made to the destination operand. (The destination operand can be a word register or a memory location; the source operand must be a word register.)

The ARPL instruction is provided for use by operating-system procedures (however, it can also be used by applications). It is generally used to adjust the RPL of a segment selector that has been passed to the operating system by an application program to match the privilege level of the application program. Here the segment selector passed to the operating system is placed in the destination operand and segment selector for the application program’s code segment is placed in the source operand. (The RPL field in the source operand represents the privilege level of the application program.) Execution of the ARPL instruction then insures that the RPL of the segment selector received by the operating system is no lower (does not have a higher privilege) than the privilege level of the application program. (The segment selector for the application program’s code segment can be read from the stack following a procedure call.)

See “Checking Caller Access Privileges” in Chapter 4 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 3*, for more information about the use of this instruction.

**Operation**

IF DEST[RPL] < SRC[RPL]  
THEN  
    ZF ← 1;  
    DEST[RPL] ← SRC[RPL];  
ELSE  
    ZF ← 0;  
FI;

**Flags Affected**

The ZF flag is set to 1 if the RPL field of the destination operand is less than that of the source operand; otherwise, is cleared to 0.
ARPL—Adjust RPL Field of Segment Selector (Continued)

Protected Mode Exceptions

#GP(0) If the destination is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#UD The ARPL instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD The ARPL instruction is not recognized in virtual-8086 mode.
BOUND—Check Array Index Against Bounds

Description

Determines if the first operand (array index) is within the bounds of an array specified the second operand (bounds operand). The array index is a signed integer located in a register. The bounds operand is a memory location that contains a pair of signed doubleword-integers (when the operand-size attribute is 32) or a pair of signed word-integers (when the operand-size attribute is 16). The first doubleword (or word) is the lower bound of the array and the second doubleword (or word) is the upper bound of the array. The array index must be greater than or equal to the lower bound and less than or equal to the upper bound plus the operand size in bytes. If the index is not within bounds, a BOUND range exceeded exception (#BR) is signaled. (When this exception is generated, the saved return instruction pointer points to the BOUND instruction.)

The bounds limit data structure (two words or doublewords containing the lower and upper limits of the array) is usually placed just before the array itself, making the limits addressable via a constant offset from the beginning of the array. Because the address of the array already will be present in a register, this practice avoids extra bus cycles to obtain the effective address of the array bounds.

Operation

IF (ArrayIndex < LowerBound OR ArrayIndex > UpperBound)
   (* Below lower bound or above upper bound *)
   THEN
       #BR;
   FI;

Flags Affected

None.

Protected Mode Exceptions

#BR If the bounds test fails.
#UD If second operand is not a memory location.
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.
BOUND—Check Array Index Against Bounds (Continued)

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#BR If the bounds test fails.

#UD If second operand is not a memory location.

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#BR If the bounds test fails.

#UD If second operand is not a memory location.

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
BSF—Bit Scan Forward

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F BC</td>
<td>BSF r16, r/m16</td>
<td>Bit scan forward on r/m16</td>
</tr>
<tr>
<td>0F BC</td>
<td>BSF r32, r/m32</td>
<td>Bit scan forward on r/m32</td>
</tr>
</tbody>
</table>

**Description**

Searches the source operand (second operand) for the least significant set bit (1 bit). If a least significant 1 bit is found, its bit index is stored in the destination operand (first operand). The source operand can be a register or a memory location; the destination operand is a register. The bit index is an unsigned offset from bit 0 of the source operand. If the contents source operand are 0, the contents of the destination operand is undefined.

**Operation**

IF SRC ← 0
    THEN
        ZF ← 1;
        DEST is undefined;
    ELSE
        ZF ← 0;
        temp ← 0;
        WHILE Bit(SRC, temp) ← 0
            DO
                temp ← temp + 1;
                DEST ← temp;
            OD;
    FI;

**Flags Affected**

The ZF flag is set to 1 if all the source operand is 0; otherwise, the ZF flag is cleared. The CF, OF, SF, AF, and PF, flags are undefined.

**Protected Mode Exceptions**

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
BSF—Bit Scan Forward (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
BSR—Bit Scan Reverse

Description
Searches the source operand (second operand) for the most significant set bit (1 bit). If a most significant 1 bit is found, its bit index is stored in the destination operand (first operand). The source operand can be a register or a memory location; the destination operand is a register. The bit index is an unsigned offset from bit 0 of the source operand. If the contents source operand are 0, the contents of the destination operand is undefined.

Operation
IF SRC ← 0
   THEN
      ZF ← 1;
      DEST is undefined;
   ELSE
      ZF ← 0;
      temp ← OperandSize − 1;
      WHILE Bit(SRC, temp) ← 0
         DO
            temp ← temp − 1;
            DEST ← temp;
         OD;
   FI;

Flags Affected
The ZF flag is set to 1 if all the source operand is 0; otherwise, the ZF flag is cleared. The CF, OF, SF, AF, and PF, flags are undefined.

Protected Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
   If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
BSR—Bit Scan Reverse (Continued)

Real-Address Mode Exceptions

#GP  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

<td>0F C8+rd</td>
<td>BSWAP r32</td>
<td>Reverses the byte order of a 32-bit register.</td>
</tr>
</tbody>
</table>

**Description**

Reverses the byte order of a 32-bit (destination) register: bits 0 through 7 are swapped with bits 24 through 31, and bits 8 through 15 are swapped with bits 16 through 23. This instruction is provided for converting little-endian values to big-endian format and vice versa.

To swap bytes in a word value (16-bit register), use the XCHG instruction. When the BSWAP instruction references a 16-bit register, the result is undefined.

**IA-32 Architecture Compatibility**

The BSWAP instruction is not supported on IA-32 processors earlier than the Intel486 processor family. For compatibility with this instruction, include functionally equivalent code for execution on Intel processors earlier than the Intel486 processor family.

**Operation**

TEMP ← DEST
DEST[7..0] ← TEMP[31..24]
DEST[15..8] ← TEMP[23..16]
DEST[23..16] ← TEMP[15..8]
DEST[31..24] ← TEMP[7..0]

**Flags Affected**

None.

**Exceptions (All Operating Modes)**

None.

**Description**

Selects the bit in a bit string (specified with the first operand, called the bit base) at the bit-position designated by the bit offset operand (second operand) and stores the value of the bit in the CF flag. The bit base operand can be a register or a memory location; the bit offset operand can be a register or an immediate value. If the bit base operand specifies a register, the instruction takes the modulo 16 or 32 (depending on the register size) of the bit offset operand, allowing any bit position to be selected in a 16- or 32-bit register, respectively (see Figure 3-1). If the bit base operand specifies a memory location, it represents the address of the byte in memory that contains the bit base (bit 0 of the specified byte) of the bit string (see Figure 3-2). The offset operand then selects a bit position within the range $-2^{31}$ to $2^{31} - 1$ for a register offset and 0 to 31 for an immediate offset.

Some assemblers support immediate bit offsets larger than 31 by using the immediate bit offset field in combination with the displacement field of the memory operand. In this case, the low-order 3 or 5 bits (3 for 16-bit operands, 5 for 32-bit operands) of the immediate bit offset are stored in the immediate bit offset field, and the high-order bits are shifted and combined with the byte displacement in the addressing mode by the assembler. The processor will ignore the high order bits if they are not zero.

When accessing a bit in memory, the processor may access 4 bytes starting from the memory address for a 32-bit operand size, using by the following relationship:

Effective Address + (4 * (BitOffset DIV 32))

Or, it may access 2 bytes starting from the memory address for a 16-bit operand, using this relationship:

Effective Address + (2 * (BitOffset DIV 16))

It may do so even when only a single byte needs to be accessed to reach the given bit. When using this bit addressing mechanism, software should avoid referencing areas of memory close to address space holes. In particular, it should avoid references to memory-mapped I/O registers. Instead, software should use the MOV instructions to load from or store to these addresses, and use the register form of these instructions to manipulate the data.

**Operation**

CF ← Bit(BitBase, BitOffset)
BT—Bit Test (Continued)

Flags Affected
The CF flag contains the value of the selected bit. The OF, SF, ZF, AF, and PF flags are undefined.

Protected Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
    If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
BTC—Bit Test and Complement

Description

Selects the bit in a bit string (specified with the first operand, called the bit base) at the bit-position designated by the bit offset operand (second operand), stores the value of the bit in the CF flag, and complements the selected bit in the bit string. The bit base operand can be a register or a memory location; the bit offset operand can be a register or an immediate value. If the bit base operand specifies a register, the instruction takes the modulo 16 or 32 (depending on the register size) of the bit offset operand, allowing any bit position to be selected in a 16- or 32-bit register, respectively (see Figure 3-1). If the bit base operand specifies a memory location, it represents the address of the byte in memory that contains the bit base (bit 0 of the specified byte) of the bit string (see Figure 3-2). The offset operand then selects a bit position within the range $-2^{31}$ to $2^{31} - 1$ for a register offset and 0 to 31 for an immediate offset.

Some assemblers support immediate bit offsets larger than 31 by using the immediate bit offset field in combination with the displacement field of the memory operand. See “BT—Bit Test” in this chapter for more information on this addressing mechanism.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation

\[
\begin{align*}
\text{CF} & \leftarrow \text{Bit(BitBase, BitOffset)} \\
\text{Bit(BitBase, BitOffset)} & \leftarrow \text{NOT Bit(BitBase, BitOffset)};
\end{align*}
\]

Flags Affected

The CF flag contains the value of the selected bit before it is complemented. The OF, SF, ZF, AF, and PF flags are undefined.

Protected Mode Exceptions

#GP(0)  If the destination operand points to a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0)  If a memory operand effective address is outside the SS segment limit.
BTC—Bit Test and Complement (Continued)

#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
BTR—Bit Test and Reset

**Description**

Selects the bit in a bit string (specified with the first operand, called the bit base) at the bit-position designated by the bit offset operand (second operand), stores the value of the bit in the CF flag, and clears the selected bit in the bit string to 0. The bit base operand can be a register or a memory location; the bit offset operand can be a register or an immediate value. If the bit base operand specifies a register, the instruction takes the modulo 16 or 32 (depending on the register size) of the bit offset operand, allowing any bit position to be selected in a 16- or 32-bit register, respectively (see Figure 3-1). If the bit base operand specifies a memory location, it represents the address of the byte in memory that contains the bit base (bit 0 of the specified byte) of the bit string (see Figure 3-2). The offset operand then selects a bit position within the range $-2^{31}$ to $2^{31} - 1$ for a register offset and 0 to 31 for an immediate offset.

Some assemblers support immediate bit offsets larger than 31 by using the immediate bit offset field in combination with the displacement field of the memory operand. See “BT—Bit Test” in this chapter for more information on this addressing mechanism.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

**Operation**

```
CF ← Bit(BitBase, BitOffset)
Bit(BitBase, BitOffset) ← 0;
```

**Flags Affected**

The CF flag contains the value of the selected bit before it is cleared. The OF, SF, ZF, AF, and PF flags are undefined.

**Protected Mode Exceptions**

* #GP(0)  
  - If the destination operand points to a nonwritable segment.
  - If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  - If the DS, ES, FS, or GS register contains a null segment selector.

* #SS(0)  
  - If a memory operand effective address is outside the SS segment limit.
BTR—Bit Test and Reset (Continued)

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

Description

Selects the bit in a bit string (specified with the first operand, called the bit base) at the bit-position designated by the bit offset operand (second operand), stores the value of the bit in the CF flag, and sets the selected bit in the bit string to 1. The bit base operand can be a register or a memory location; the bit offset operand can be a register or an immediate value. If the bit base operand specifies a register, the instruction takes the modulo 16 or 32 (depending on the register size) of the bit offset operand, allowing any bit position to be selected in a 16- or 32-bit register, respectively (see Figure 3-1). If the bit base operand specifies a memory location, it represents the address of the byte in memory that contains the bit base (bit 0 of the specified byte) of the bit string (see Figure 3-2). The offset operand then selects a bit position within the range $-2^{31}$ to $2^{31} - 1$ for a register offset and 0 to 31 for an immediate offset.

Some assemblers support immediate bit offsets larger than 31 by using the immediate bit offset field in combination with the displacement field of the memory operand. See “BT—Bit Test” in this chapter for more information on this addressing mechanism.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation

$$CF \leftarrow \text{Bit(BitBase, BitOffset)}$$

$$\text{Bit(BitBase, BitOffset)} \leftarrow 1;$$

Flags Affected

The CF flag contains the value of the selected bit before it is set. The OF, SF, ZF, AF, and PF flags are undefined.

Protected Mode Exceptions

#GP(0) If the destination operand points to a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

Description

Saves procedure linking information on the stack and branches to the procedure (called procedure) specified with the destination (target) operand. The target operand specifies the address of the first instruction in the called procedure. This operand can be an immediate value, a general-purpose register, or a memory location.

This instruction can be used to execute four different types of calls:

- Near call—A call to a procedure within the current code segment (the segment currently pointed to by the CS register), sometimes referred to as an intrasegment call.
- Far call—A call to a procedure located in a different segment than the current code segment, sometimes referred to as an intersegment call.
- Inter-privilege-level far call—A far call to a procedure in a segment at a different privilege level than that of the currently executing program or procedure.
- Task switch—A call to a procedure located in a different task.

The latter two call types (inter-privilege-level call and task switch) can only be executed in protected mode. See the section titled “Calling Procedures Using Call and RET” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for additional information on near, far, and inter-privilege-level calls. See Chapter 6, Task Management, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for information on performing task switches with the CALL instruction.

Near Call. When executing a near call, the processor pushes the value of the EIP register (which contains the offset of the instruction following the CALL instruction) onto the stack (for use later as a return-instruction pointer). The processor then branches to the address in the current code segment specified with the target operand. The target operand specifies either an absolute offset in the code segment (that is an offset from the base of the code segment) or a relative offset (a signed displacement relative to the current value of the instruction pointer in the EIP register, which points to the instruction following the CALL instruction). The CS register is not changed on near calls.
CALL—Call Procedure (Continued)

For a near call, an absolute offset is specified indirectly in a general-purpose register or a memory location (r/m16 or r/m32). The operand-size attribute determines the size of the target operand (16 or 32 bits). Absolute offsets are loaded directly into the EIP register. If the operand-size attribute is 16, the upper two bytes of the EIP register are cleared to 0s, resulting in a maximum instruction pointer size of 16 bits. (When accessing an absolute offset indirectly using the stack pointer [ESP] as a base register, the base value used is the value of the ESP before the instruction executes.)

A relative offset (rel16 or rel32) is generally specified as a label in assembly code, but at the machine code level, it is encoded as a signed, 16- or 32-bit immediate value. This value is added to the value in the EIP register. As with absolute offsets, the operand-size attribute determines the size of the target operand (16 or 32 bits).

Far Calls in Real-Address or Virtual-8086 Mode. When executing a far call in real-address or virtual-8086 mode, the processor pushes the current value of both the CS and EIP registers onto the stack for use as a return-instruction pointer. The processor then performs a “far branch” to the code segment and offset specified with the target operand for the called procedure. Here the target operand specifies an absolute far address either directly with a pointer (ptr16:16 or ptr16:32) or indirectly with a memory location (m16:16 or m16:32). With the pointer method, the segment and offset of the called procedure is encoded in the instruction, using a 4-byte (16-bit operand size) or 6-byte (32-bit operand size) far address immediate. With the indirect method, the target operand specifies a memory location that contains a 4-byte (16-bit operand size) or 6-byte (32-bit operand size) far address. The operand-size attribute determines the size of the offset (16 or 32 bits) in the far address. The far address is loaded directly into the CS and EIP registers. If the operand-size attribute is 16, the upper two bytes of the EIP register are cleared to 0s.

Far Calls in Protected Mode. When the processor is operating in protected mode, the CALL instruction can be used to perform the following three types of far calls:

- Far call to the same privilege level.
- Far call to a different privilege level (inter-privilege level call).
- Task switch (far call to another task).

In protected mode, the processor always uses the segment selector part of the far address to access the corresponding descriptor in the GDT or LDT. The descriptor type (code segment, call gate, task gate, or TSS) and access rights determine the type of call operation to be performed.

If the selected descriptor is for a code segment, a far call to a code segment at the same privilege level is performed. (If the selected code segment is at a different privilege level and the code segment is non-conforming, a general-protection exception is generated.) A far call to the same privilege level in protected mode is very similar to one carried out in real-address or virtual-8086 mode. The target operand specifies an absolute far address either directly with a pointer (ptr16:16 or ptr16:32) or indirectly with a memory location (m16:16 or m16:32). The operand-size attribute determines the size of the offset (16 or 32 bits) in the far address. The new code segment selector and its descriptor are loaded into CS register, and the offset from the instruction is loaded into the EIP register.
CALL—Call Procedure (Continued)

Note that a call gate (described in the next paragraph) can also be used to perform far call to a code segment at the same privilege level. Using this mechanism provides an extra level of indirection and is the preferred method of making calls between 16-bit and 32-bit code segments.

When executing an inter-privilege-level far call, the code segment for the procedure being called must be accessed through a call gate. The segment selector specified by the target operand identifies the call gate. Here again, the target operand can specify the call gate segment selector either directly with a pointer ($ptr16:16$ or $ptr16:32$) or indirectly with a memory location ($m16:16$ or $m16:32$). The processor obtains the segment selector for the new code segment and the new instruction pointer (offset) from the call gate descriptor. (The offset from the target operand is ignored when a call gate is used.) On inter-privilege-level calls, the processor switches to the stack for the privilege level of the called procedure. The segment selector for the new stack segment is specified in the TSS for the currently running task. The branch to the new code segment occurs after the stack switch. (Note that when using a call gate to perform a far call to a segment at the same privilege level, no stack switch occurs.) On the new stack, the processor pushes the segment selector and stack pointer for the calling procedure’s stack, an (optional) set of parameters from the calling procedure’s stack, and the segment selector and instruction pointer for the calling procedure’s code segment. (A value in the call gate descriptor determines how many parameters to copy to the new stack.) Finally, the processor branches to the address of the procedure being called within the new code segment.

Executing a task switch with the CALL instruction, is somewhat similar to executing a call through a call gate. Here the target operand specifies the segment selector of the task gate for the task being switched to (and the offset in the target operand is ignored.) The task gate in turn points to the TSS for the task, which contains the segment selectors for the task’s code and stack segments. The TSS also contains the EIP value for the next instruction that was to be executed before the task was suspended. This instruction pointer value is loaded into EIP register so that the task begins executing again at this next instruction.

The CALL instruction can also specify the segment selector of the TSS directly, which eliminates the indirection of the task gate. See Chapter 6, Task Management, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for detailed information on the mechanics of a task switch.

Note that when you execute at task switch with a CALL instruction, the nested task flag (NT) is set in the EFLAGS register and the new TSS’s previous task link field is loaded with the old tasks TSS selector. Code is expected to suspend this nested task by executing an IRET instruction, which, because the NT flag is set, will automatically use the previous task link to return to the calling task. (See “Task Linking” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for more information on nested tasks.) Switching tasks with the CALL instruction differs in this regard from the JMP instruction which does not set the NT flag and therefore does not expect an IRET instruction to suspend the task.
CALL—Call Procedure (Continued)

Mixing 16-Bit and 32-Bit Calls. When making far calls between 16-bit and 32-bit code segments, the calls should be made through a call gate. If the far call is from a 32-bit code segment to a 16-bit code segment, the call should be made from the first 64 KBytes of the 32-bit code segment. This is because the operand-size attribute of the instruction is set to 16, so only a 16-bit return address offset is saved. Also, the call should be made using a 16-bit call gate so that 16-bit values will be pushed on the stack. See Chapter 16, Mixing 16-Bit and 32-Bit Code, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for more information on making calls between 16-bit and 32-bit code segments.

Flags Affected
All flags are affected if a task switch occurs; no flags are affected if a task switch does not occur.
CALL—Call Procedure (Continued)

Protected Mode Exceptions

#GP(0)  If target offset in destination operand is beyond the new code segment limit.
If the segment selector in the destination operand is null.
If the code segment selector in the gate is null.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#GP(selector)  If code segment or gate or TSS selector index is outside descriptor table limits.
If the segment descriptor pointed to by the segment selector in the destination operand is not for a conforming-code segment, nonconforming-code segment, call gate, task gate, or task state segment.
If the DPL for a nonconforming-code segment is not equal to the CPL or the RPL for the segment’s segment selector is greater than the CPL.
If the DPL for a conforming-code segment is greater than the CPL.
If the DPL from a call-gate, task-gate, or TSS segment descriptor is less than the CPL or than the RPL of the call-gate, task-gate, or TSS’s segment selector.
If the segment descriptor for a segment selector from a call gate does not indicate it is a code segment.
If the segment selector from a call gate is beyond the descriptor table limits.
If the DPL for a code-segment obtained from a call gate is greater than the CPL.
If the segment selector for a TSS has its local/global bit set for local.
If a TSS segment descriptor specifies that the TSS is busy or not available.

#SS(0)  If pushing the return address, parameters, or stack segment pointer onto the stack exceeds the bounds of the stack segment, when no stack switch occurs.
If a memory operand effective address is outside the SS segment limit.

#SS(selector)  If pushing the return address, parameters, or stack segment pointer onto the stack exceeds the bounds of the stack segment, when a stack switch occurs.
CALL—Call Procedure (Continued)

If the SS register is being loaded as part of a stack switch and the segment pointed to is marked not present.
If stack segment does not have room for the return address, parameters, or stack segment pointer, when stack switch occurs.

#NP(selector) If a code segment, data segment, stack segment, call gate, task gate, or TSS is not present.
#TS(selector) If the new stack segment selector and ESP are beyond the end of the TSS.
If the new stack segment selector is null.
If the RPL of the new stack segment selector in the TSS is not equal to the DPL of the code segment being accessed.
If DPL of the stack segment descriptor for the new stack segment is not equal to the DPL of the code segment descriptor.
If the new stack segment is not a writable data segment.
If segment-selector index for stack segment is outside descriptor table limits.

#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the target offset is beyond the code segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the target offset is beyond the code segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
CBW/CWDE—Convert Byte to Word/Convert Word to Doubleword

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>98</td>
<td>CBW</td>
<td>AX ← sign-extend of AL</td>
</tr>
<tr>
<td>98</td>
<td>CWDE</td>
<td>EAX ← sign-extend of AX</td>
</tr>
</tbody>
</table>

**Description**

Double the size of the source operand by means of sign extension (see Figure 7-6 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*). The CBW (convert byte to word) instruction copies the sign (bit 7) in the source operand into every bit in the AH register. The CWDE (convert word to doubleword) instruction copies the sign (bit 15) of the word in the AX register into the higher 16 bits of the EAX register.

The CBW and CWDE mnemonics reference the same opcode. The CBW instruction is intended for use when the operand-size attribute is 16 and the CWDE instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when CBW is used and to 32 when CWDE is used. Others may treat these mnemonics as synonyms (CBW/CWDE) and use the current setting of the operand-size attribute to determine the size of values to be converted, regardless of the mnemonic used.

The CWDE instruction is different from the CWD (convert word to double) instruction. The CWD instruction uses the DX:AX register pair as a destination operand; whereas, the CWDE instruction uses the EAX register as a destination.

**Operation**

IF OperandSize ← 16 (* instruction ← CBW *)
    THEN AX ← SignExtend(AL);
    ELSE (* OperandSize ← 32, instruction ← CWDE *)
        EAX ← SignExtend(AX);
FI;

**Flags Affected**

None.

**Exceptions (All Operating Modes)**

None.
CDQ—Convert Double to Quad
See entry for CWD/CDQ — Convert Word to Doubleword/Convert Doubleword to Quadword.
CLC—Clear Carry Flag

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8</td>
<td>CLC</td>
<td>Clear CF flag</td>
</tr>
</tbody>
</table>

**Description**

Clears the CF flag in the EFLAGS register.

**Operation**

CF ← 0;

**Flags Affected**

The CF flag is cleared to 0. The OF, ZF, SF, AF, and PF flags are unaffected.

**Exceptions (All Operating Modes)**

None.
CLD—Clear Direction Flag

Description
Clears the DF flag in the EFLAGS register. When the DF flag is set to 0, string operations increment the index registers (ESI and/or EDI).

Operation
DF ← 0;

Flags Affected
The DF flag is cleared to 0. The CF, OF, ZF, SF, AF, and PF flags are unaffected.

Exceptions (All Operating Modes)
None.
CLFLUSH—Flush Cache Line

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F  AE /7</td>
<td>CLFLUSH m8</td>
<td>Flushes cache line containing m8.</td>
</tr>
</tbody>
</table>

**Description**

Invalidates the cache line that contains the linear address specified with the source operand from all levels of the processor cache hierarchy (data and instruction). The invalidation is broadcast throughout the cache coherence domain. If, at any level of the cache hierarchy, the line is inconsistent with memory (dirty) it is written to memory before invalidation. The source operand is a byte memory location.

The availability of the CLFLUSH is indicated by the presence of the CPUID feature flag CLFSH (bit 19 of the EDX register, see Section , CPUID—CPU Identification). The aligned cache line size affected is also indicated with the CPUID instruction (bits 8 through 15 of the EBX register when the initial value in the EAX register is 1).

The memory attribute of the page containing the affected line has no effect on the behavior of this instruction. It should be noted that processors are free to speculatively fetch and cache data from system memory regions assigned a memory-type allowing for speculative reads (such as, the WB, WC, WT memory types). PREFETCHh instructions can be used to provide the processor with hints for this speculative behavior. Because this speculative fetching can occur at any time and is not tied to instruction execution, the CLFLUSH instruction is not ordered with respect to PREFETCHh instructions or any of the speculative fetching mechanisms (that is, data can be speculatively loaded into a cache line just before, during, or after the execution of a CLFLUSH instruction that references the cache line).

CLFLUSH is only ordered by the MFENCE instruction. It is not guaranteed to be ordered by any other fencing or serializing instructions or by another CLFLUSH instruction. For example, software can use an MFENCE instruction to insure that previous stores are included in the write-back.

The CLFLUSH instruction can be used at all privilege levels and is subject to all permission checking and faults associated with a byte load (and in addition, a CLFLUSH instruction is allowed to flush a linear address in an execute-only segment). Like a load, the CLFLUSH instruction sets the A bit but not the D bit in the page tables.

The CLFLUSH instruction was introduced with the SSE2 extensions; however, because it has its own CPUID feature flag, it can be implemented in IA-32 processors that do not include the SSE2 extensions. Also, detecting the presence of the SSE2 extensions with the CPUID instruction does not guarantee that the CLFLUSH instruction is implemented in the processor.

**Operation**

Flush_Cache_Line(SRC)
CLFLUSH—Cache Line Flush (Continued)

**Intel C/C++ Compiler Intrinsic Equivalents**

CLFLUSH    void_mm_clflush(void const *p)

**Protected Mode Exceptions**

#GP(0)        For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
#SS(0)        For an illegal address in the SS segment.
#PF(fault-code) For a page fault.
#UD            If CPUID feature flag CLFSH is 0.

**Real-Address Mode Exceptions**

Interrupt 13    If any part of the operand lies outside the effective address space from 0 to FFFFH.
#UD            If CPUID feature flag CLFSH is 0.

**Virtual-8086 Mode Exceptions**

Same exceptions as in Real Address Mode
#PF(fault-code) For a page fault.
CLI—Clear Interrupt Flag

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FA</td>
<td>CLI</td>
<td>Clear interrupt flag; interrupts disabled when interrupt flag cleared</td>
</tr>
</tbody>
</table>

Description

Clears the IF flag in the EFLAGS register. No other flags are affected. Clearing the IF flag causes the processor to ignore maskable external interrupts. The IF flag and the CLI and STI instruction have no affect on the generation of exceptions and NMI interrupts.

The following decision table indicates the action of the CLI instruction (bottom of the table) depending on the processor’s mode of operating and the CPL and IOPL of the currently running program or procedure (top of the table).

<table>
<thead>
<tr>
<th>PE = 0</th>
<th>VM = X</th>
<th>CPL ≤ IOPL</th>
<th>CPL &gt; IOPL</th>
<th>IOPL = 3</th>
<th>IOPL &lt; 3</th>

<td>Y</td>
<td>N</td>
</tr>
</tbody>
</table>

NOTES:
X Don’t care
N Action in column 1 not taken
Y Action in column 1 taken

Operation

IF PE ← 0 (* Executing in real-address mode *)
THEN
   IF ← 0;
ELSE
   IF VM ← 0 (* Executing in protected mode *)
   THEN
       IF CPL ≤ IOPL
       THEN
           IF ← 0;
       ELSE
           #GP(0);
       FI;
   FI;
CLI—Clear Interrupt Flag (Continued)

ELSE (* Executing in Virtual-8086 mode *)
    IF IOPL ← 3
    THEN
        IF ← 0
        ELSE
            #GP(0);
            FI;
    FI;
FI;

Flags Affected

The IF is cleared to 0 if the CPL is equal to or less than the IOPL; otherwise, it is not affected. The other flags in the EFLAGS register are unaffected.

Protected Mode Exceptions

#GP(0) If the CPL is greater (has less privilege) than the IOPL of the current program or procedure.

Real-Address Mode Exceptions

None.

Virtual-8086 Mode Exceptions

#GP(0) If the CPL is greater (has less privilege) than the IOPL of the current program or procedure.
CLTS—Clear Task-Switched Flag in CR0

Description
Clears the task-switched (TS) flag in the CR0 register. This instruction is intended for use in operating-system procedures. It is a privileged instruction that can only be executed at a CPL of 0. It is allowed to be executed in real-address mode to allow initialization for protected mode.

The processor sets the TS flag every time a task switch occurs. The flag is used to synchronize the saving of FPU context in multitasking applications. See the description of the TS flag in the section titled “Control Registers” in Chapter 2 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for more information about this flag.

Operation
CR0(TS) ← 0;

Flags Affected
The TS flag in CR0 register is cleared.

Protected Mode Exceptions
#GP(0) If the CPL is greater than 0.

Real-Address Mode Exceptions
None.

Virtual-8086 Mode Exceptions
#GP(0) If the CPL is greater than 0.
CMC—Complement Carry Flag

Description
Complements the CF flag in the EFLAGS register.

Operation
CF ← NOT CF;

Flags Affected
The CF flag contains the complement of its original value. The OF, ZF, SF, AF, and PF flags are unaffected.

Exceptions (All Operating Modes)
None.

CMOVcc—Conditional Move (Continued)

### Description

The CMOVcc instructions check the state of one or more of the status flags in the EFLAGS register (CF, OF, PF, SF, and ZF) and perform a move operation if the flags are in a specified state (or condition). A condition code (cc) is associated with each instruction to indicate the condition being tested for. If the condition is not satisfied, a move is not performed and execution continues with the instruction following the CMOVcc instruction.

These instructions can move a 16- or 32-bit value from memory to a general-purpose register or from one general-purpose register to another. Conditional moves of 8-bit register operands are not supported.

The conditions for each CMOVcc mnemonic is given in the description column of the above table. The terms “less” and “greater” are used for comparisons of signed integers and the terms “above” and “below” are used for unsigned integers.

Because a particular state of the status flags can sometimes be interpreted in two ways, two mnemonics are defined for some opcodes. For example, the CMOVA (conditional move if above) instruction and the CMOVNBE (conditional move if not below or equal) instruction are alternate mnemonics for the opcode 0F 47H.
CMOVcc—Conditional Move (Continued)

The CMOVcc instructions are new for the Pentium Pro processor family; however, they may not be supported by all the processors in the family. Software can determine if the CMOVcc instructions are supported by checking the processor’s feature information with the CPUID instruction (see “COMISS—Compare Scalar Ordered Single-Precision Floating-Point Values and Set EFLAGS” in this chapter).

**Operation**

\[
\text{temp} \leftarrow \text{DEST} \\
\text{IF condition TRUE} \\
\quad \text{THEN} \\
\quad \text{DEST} \leftarrow \text{SRC} \\
\quad \text{ELSE} \\
\quad \text{DEST} \leftarrow \text{temp} \\
\text{FI;}
\]

**Flags Affected**

None.

**Protected Mode Exceptions**

- **#GP(0)** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  - If the DS, ES, FS, or GS register contains a null segment selector.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
- **#PF(fault-code)** If a page fault occurs.
- **#AC(0)** If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

**Real-Address Mode Exceptions**

- **#GP** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS** If a memory operand effective address is outside the SS segment limit.

**Virtual-8086 Mode Exceptions**

- **#GP(0)** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
CMOVcc—Conditional Move (Continued)

#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
CMP—Compare Two Operands

Description

Compares the first source operand with the second source operand and sets the status flags in the EFLAGS register according to the results. The comparison is performed by subtracting the second operand from the first operand and then setting the status flags in the same manner as the SUB instruction. When an immediate value is used as an operand, it is sign-extended to the length of the first operand.

The CMP instruction is typically used in conjunction with a conditional jump (Jcc), condition move (CMOVcc), or SETcc instruction. The condition codes used by the Jcc, CMOVcc, and SETcc instructions are based on the results of a CMP instruction. Appendix B, EFLAGS Condition Codes, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, shows the relationship of the status flags and the condition codes.

Operation

temp ← SRC1 − SignExtend(SRC2);
ModifyStatusFlags; (* Modify status flags in the same manner as the SUB instruction*)

Flags Affected

The CF, OF, SF, ZF, AF, and PF flags are set according to the result.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

<td>CMPPD xmm1, xmm2/m128, imm8</td>
<td>Compare packed double-precision floating-point values in xmm2/m128 and xmm1 using imm8 as comparison predicate.</td>
</tr>
</tbody>
</table>

Description

Performs a SIMD compare of the two packed double-precision floating-point values in the source operand (second operand) and the destination operand (first operand) and returns the results of the comparison to the destination operand. The comparison predicate operand (third operand) specifies the type of comparison performed on each of the pairs of packed values. The result of each comparison is a quadword mask of all 1s (comparison true) or all 0s (comparison false). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The comparison predicate operand is an 8-bit immediate the first 3 bits of which define the type of comparison to be made (see Table 3-5); bits 4 through 7 of the immediate are reserved.

CMPPD—Compare Packed Double-Precision Floating-Point Values (Continued)

The unordered relationship is true when at least one of the two source operands being compared is a NaN or in an undefined format. The ordered relationship is true when neither source operand is a NaN or in an undefined format.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate an exception, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Note that the processor does not implement the greater-than, greater-than-or-equal, not-greater-than, and not-greater-than-or-equal relations. These comparisons can be made either by using the inverse relationship (that is, use the “not-less-than-or-equal” to make a “greater-than” comparison) or by using software emulation. When using software emulation, the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in Table 3-5 under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPPD instruction.

<table>
<thead>
<tr>

</tbody>
</table>

The greater-than relations that the processor does not implement require more than one instruction to emulate in software and therefore should not be implemented as pseudo-ops. (For these, the programmer should reverse the operands of the corresponding less than relations and use move instructions to ensure that the mask is moved to the correct destination register and that the source operand is left intact.)

If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE2 is 0.

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.

Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE2 is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
CMPPS—Compare Packed Single-Precision Floating-Point Values

**Description**

Performs a SIMD compare of the four packed single-precision floating-point values in the source operand (second operand) and the destination operand (first operand) and returns the results of the comparison to the destination operand. The comparison predicate operand (third operand) specifies the type of comparison performed on each of the pairs of packed values. The result of each comparison is a doubleword mask of all 1s (comparison true) or all 0s (comparison false). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The comparison predicate operand is an 8-bit immediate the first 3 bits of which define the type of comparison to be made (see Table 3-5); bits 4 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN or in an undefined format. The ordered relationship is true when neither source operand is a NaN or in an undefined format.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate a fault, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Some of the comparisons listed in Table 3-5 (such as the greater-than, greater-than-or-equal, not-greater-than, and not-greater-than-or-equal relations) can be made only through software emulation. For these comparisons the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in Table 3-5 under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operands CMPPS instruction:

<table>
<thead>
<tr>

CMPS/CMPSB/CMPSW/CMPSD—Compare String Operands

**Description**

Compares the byte, word, or double word specified with the first source operand with the byte, word, or double word specified with the second source operand and sets the status flags in the EFLAGS register according to the results. Both the source operands are located in memory. The address of the first source operand is read from either the DS:ESI or the DS:SI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). The address of the second source operand is read from either the ES:EDI or the ES:DI registers (again depending on the address-size attribute of the instruction). The DS segment may be overridden with a segment override prefix, but the ES segment cannot be overridden.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the CMPS mnemonic) allows the two source operands to be specified explicitly. Here, the source operands should be symbols that indicate the size and location of the source values. This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the source operand symbols must specify the correct type (size) of the operands (bytes, words, or doublewords), but they do not have to specify the correct location. The locations of the source operands are always specified by the DS:(E)SI and ES:(E)DI registers, which must be loaded correctly before the compare string instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the CMPS instructions. Here also the DS:(E)SI and ES:(E)DI registers are assumed by the processor to specify the location of the source operands. The size of the source operands is selected with the mnemonic: CMPSB (byte comparison), CMPSW (word comparison), or CMPSD (double-word comparison).

</tr>
</tbody>
</table>
CMPS/CMPSB/CMPSW/CMPSD—Compare String Operands

(Continued)

After the comparison, the (E)SI and (E)DI registers are incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)SI and (E)DI register are incremented; if the DF flag is 1, the (E)SI and (E)DI registers are decremented.) The registers are incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.

The CMPS, CMPSB, CMPSW, and CMPSD instructions can be preceded by the REP prefix for block comparisons of ECX bytes, words, or doublewords. More often, however, these instructions will be used in a LOOP construct that takes some action based on the setting of the status flags before the next comparison is made. See “REP/REPE/REPZ/REPNZ/REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.

Flags Affected
The CF, OF, SF, ZF, AF, and PF flags are set according to the temporary result of the comparison.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
CMPSD—Compare Scalar Double-Precision Floating-Point Values

**Description**

Compares the low double-precision floating-point values in the source operand (second operand) and the destination operand (first operand) and returns the results of the comparison to the destination operand. The comparison predicate operand (third operand) specifies the type of comparison performed. The comparison result is a quadword mask of all 1s (comparison true) or all 0s (comparison false). The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. The result is stored in the low quadword of the destination operand; the high quadword remains unchanged. The comparison predicate operand is an 8-bit immediate the first 3 bits of which define the type of comparison to be made (see Table 3-5); bits 4 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN or in an undefined format. The ordered relationship is true when neither source operand is a NaN or in an undefined format.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate a fault, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Some of the comparisons listed in Table 3-5 can be achieved only through software emulation. For these comparisons the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination operand), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in Table 3-5 under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPSD instruction.

<td>CMPSS xmm1, xmm2/m32, imm8</td>
<td>Compare low single-precision floating-point value in xmm2/m32 and xmm1 using imm8 as comparison predicate.</td>
</tr>
</tbody>
</table>

**Description**

Compares the low single-precision floating-point values in the source operand (second operand) and the destination operand (first operand) and returns the results of the comparison to the destination operand. The comparison predicate operand (third operand) specifies the type of comparison performed. The comparison result is a doubleword mask of all 1s (comparison true) or all 0s (comparison false). The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The result is stored in the low doubleword of the destination operand; the 3 high-order doublewords remain unchanged. The comparison predicate operand is an 8-bit immediate the first 3 bits of which define the type of comparison to be made (see Table 3-5); bits 4 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN or in an undefined format. The ordered relationship is true when neither source operand is a NaN or in an undefined format.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate a fault, since a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Some of the comparisons listed in Table 3-5 can be achieved only through software emulation. For these comparisons the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination operand), and then perform the compare using a different predicate. CMPXCHG—Compare and Exchange

Description

Compares the value in the AL, AX, or EAX register (depending on the size of the operand) with the first operand (destination operand). If the two values are equal, the second operand (source operand) is loaded into the destination operand. Otherwise, the destination operand is loaded into the AL, AX, or EAX register.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically. To simplify the interface to the processor’s bus, the destination operand receives a write cycle without regard to the result of the comparison. The destination operand is written back if the comparison fails; otherwise, the source operand is written into the destination. (The processor never produces a locked read without also producing a locked write.)

IA-32 Architecture Compatibility

This instruction is not supported on Intel processors earlier than the Intel486 processors.

Operation

(* accumulator ← AL, AX, or EAX, depending on whether *)
(* a byte, word, or doubleword comparison is being performed*)

IF accumulator ← DEST
    THEN
        ZF ← 1
        DEST ← SRC
    ELSE
        ZF ← 0
        accumulator ← DEST
FI;

Flags Affected

The ZF flag is set if the values in the destination operand and register AL, AX, or EAX are equal; otherwise it is cleared. The CF, PF, AF, SF, and OF flags are set according to the results of the comparison operation.
CMPXCHG—Compare and Exchange (Continued)

Protected Mode Exceptions

#GP(0) If the destination is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
CMPXCHG8B—Compare and Exchange 8 Bytes

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F C7 /1 m64</td>
<td>CMPXCHG8B m64</td>
<td>Compare EDX:EAX with m64. If equal, set ZF and load ECX:EBX into m64. Else, clear ZF and load m64 into EDX:EAX.</td>
</tr>
</tbody>
</table>

**Description**

Compares the 64-bit value in EDX:EAX with the operand (destination operand). If the values are equal, the 64-bit value in ECX:EBX is stored in the destination operand. Otherwise, the value in the destination operand is loaded into EDX:EAX. The destination operand is an 8-byte memory location. For the EDX:EAX and ECX:EBX register pairs, EDX and ECX contain the high-order 32 bits and EAX and EBX contain the low-order 32 bits of a 64-bit value.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically. To simplify the interface to the processor’s bus, the destination operand receives a write cycle without regard to the result of the comparison. The destination operand is written back if the comparison fails; otherwise, the source operand is written into the destination. (The processor never produces a locked read without also producing a locked write.)

**IA-32 Architecture Compatibility**

This instruction is not supported on Intel processors earlier than the Pentium processors.

**Operation**

IF (EDX:EAX ← DEST)
    ZF ← 1
    DEST ← ECX:EBX
ELSE
    ZF ← 0
    EDX:EAX ← DEST

**Flags Affected**

The ZF flag is set if the destination operand and EDX:EAX are equal; otherwise it is cleared. The CF, PF, AF, SF, and OF flags are unaffected.
CMPXCHG8B—Compare and Exchange 8 Bytes (Continued)

Protected Mode Exceptions

#UD If the destination operand is not a memory location.
#GP(0) If the destination is located in a nonwritable segment.
    If a memory operand effective address is outside the CS, DS, ES, FS, or
    GS segment limit.
    If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
    made while the current privilege level is 3.

Real-Address Mode Exceptions

#UD If the destination operand is not a memory location.
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or
    GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#UD If the destination operand is not a memory location.
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or
    GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
    made.
INSTRUCTION SET REFERENCE

COMISD—Compare Scalar Ordered Double-Precision Floating-Point Values and Set EFLAGS

Description

Compares the double-precision floating-point values in the low quadwords of source operand 1 (first operand) and source operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Source operand 1 is an XMM register; source operand 2 can be an XMM register or a 64 bit memory location.

The COMISD instruction differs from the UCOMISD instruction in that it signals a SIMD floating-point invalid operation exception (#I) when a source operand is either a QNaN or SNaN. The UCOMISD instruction signals an invalid numeric exception only if a source operand is an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Operation

RESULT ← OrderedCompare(DEST[63-0] <> SRC[63-0]) {
    * Set EFLAGS *CASE (RESULT) OF
        UNORDERED: ZF,PF,CF ← 111;
        GREATER_THAN: ZF,PF,CF ← 000;
        LESS_THAN: ZF,PF,CF ← 001;
        EQUAL: ZF,PF,CF ← 100;
    ESAC;
    OF,AF,SF ← 0;
}

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
COMISS—Compare Scalar Ordered Single-Precision Floating-Point Values and Set EFLAGS

**Description**

Compares the single-precision floating-point values in the low doublewords of source operand 1 (first operand) and the source operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Source operand 1 is an XMM register; source operand 2 can be an XMM register or a 32 bit memory location.

The COMISS instruction differs from the UCOMISS instruction in that it signals a SIMD floating-point invalid operation exception (#I) when a source operand is either a QNaN or SNaN. The UCOMISS instruction signals an invalid numeric exception only if a source operand is an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

**Operation**

RESULT ← OrderedCompare(SRC1[31-0] <> SRC2[31-0]) {
  * Set EFLAGS *CASE (RESULT) OF

CPUID—CPU Identification

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F A2</td>
<td>CPUID</td>
<td>Returns processor identification and feature information to the EAX, EBX, ECX, and EDX registers, according to the input value entered initially in the EAX register</td>
</tr>
</tbody>
</table>

Description

Returns processor identification and feature information in the EAX, EBX, ECX, and EDX registers. The information returned is selected by entering a value in the EAX register before the instruction is executed. Table 3-6 shows the information returned, depending on the initial value loaded into the EAX register.

The ID flag (bit 21) in the EFLAGS register indicates support for the CPUID instruction. If a software procedure can set and clear this flag, the processor executing the procedure supports the CPUID instruction.

The information returned with the CPUID instruction is divided into two groups: basic information and extended function information. Basic information is returned by entering an input value of from 0 to 3 in the EAX register depending on the IA-32 processor type; extended function information is returned by entering an input value of from 80000000H to 80000004H. The extended function CPUID information was introduced with the Pentium 4 processors and is not available in earlier IA-32 processors. Table 3-7 shows the maximum input value that the processor recognizes for the CPUID instruction for basic information and for extended function information, for each family of IA-32 processors on which the CPUID instruction is implemented.

If a higher value than is shown in Table 3-6 is entered for a particular processor, the information for the highest useful basic information value is returned. For example, if an input value of 5 is entered in EAX for a Pentium 4 processor, the information for an input value of 2 is returned. The exception to this rule is the input values that return extended function information (currently, the values 80000000H through 80000004H). For a Pentium 4 processor, entering an input value of 80000005H or above, returns the information for an input value of 2.

The CPUID instruction can be executed at any privilege level to serialize instruction execution. Serializing instruction execution guarantees that any modifications to flags, registers, and memory for previous instructions are completed before the next instruction is fetched and executed (see “Serializing Instructions” in Chapter 7 of the IA-32 Intel Architecture Software Developer's Manual, Volume 3).

When the input value in the EAX register is 0, the processor returns the highest value the CPUID instruction recognizes in the EAX register for returning basic CPUID information (see Table 3-7). A vendor identification string is returned in the EBX, EDX, and ECX registers. For Intel processors, the vendor identification string is “GenuineIntel” as follows:

EBX ← 756e6547h (* "Genu", with G in the low nibble of BL *)
EDX ← 49656e69h (* "ineI", with i in the low nibble of DL *)
ECX ← 6c65746eh (* "ntel", with n in the low nibble of CL *)

INSTRUCTION SET REFERENCE

CPUID—CPU Identification (Continued)

When the input value is 1, the processor returns version information in the EAX register (see Figure 3-3). The version information consists of an IA-32 processor family identifier, a model identifier, a stepping ID, and a processor type. The model, family, and processor type for the first processor in the Intel Pentium 4 family is as follows:

- **Model**—0000B
- **Family**—1111B
- **Processor Type**—00B

The available processor types are given in Table 3-8. Intel releases information on stepping IDs as needed.

![Figure 3-3. Version Information in the EAX Register](image-url)
CPUID—CPU Identification (Continued)

If the values in the family and/or model fields reach or exceed FH, the CPUID instruction will generate two additional fields in the EAX register: the extended family field and the extended model field. Here, a value of FH in either the model field or the family field indicates that the extended model or family field, respectively, is valid. Family and model numbers beyond FH range from 0FH to FFH, with the least significant hexadecimal digit always FH.

See AP-485, Intel Processor Identification and the CPUID Instruction (Order Number 241618) and Chapter 13 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1, for more information on identifying earlier IA-32 processors.

When the input value in EAX is 1, three unrelated pieces of information are returned to the EBX register:

- Brand index (low byte of EBX)—this number provides an entry into a brand string table that contains brand strings for IA-32 processors. See “Brand Identification” later in the description of this instruction for information about the intended use of brand indices. This field was introduced in the Pentium® III Xeon™ processors.
- CLFLUSH instruction cache line size (second byte of EBX)—this number indicates the size of the cache line flushed with CLFLUSH instruction in 8-byte increments. This field was introduced with the Pentium 4 processors.
- Initial APIC ID (high byte of EBX)—this number is the 8-bit physical ID that is assigned to the local APIC on the processor during power up. This field was introduced with the Pentium 4 processors.
When the input value in EAX is 1, feature information is returned to the EDX register (see Figure 3-4). The feature bits permit operating system or application code to determine which IA-32 architectural features are available in the processor. Table 3-9 shows the encoding of the feature flags in the EDX register. For all the feature flags currently returned in EDX, a 1 indicates that the corresponding feature is supported. Software should identify Intel as the vendor to properly interpret the feature flags. (Software should not depend on a 1 indicating the presence of a feature for future feature flags.)

CPUID—CPU Identification (Continued)

When the input value is 2, the processor returns information about the processor’s internal caches and TLBs in the EAX, EBX, ECX, and EDX registers. The encoding of these registers is as follows:

- The least-significant byte in register EAX (register AL) indicates the number of times the CPUID instruction must be executed with an input value of 2 to get a complete description of the processor’s caches and TLBs. The first member of the family of Pentium 4 processors will return a 1.
- The most significant bit (bit 31) of each register indicates whether the register contains valid information (cleared to 0) or is reserved (set to 1).
- If a register contains valid information, the information is contained in 1 byte descriptors. Table 3-10 shows the encoding of these descriptors. Note that the order of descriptors in the EAX, EBX, ECX, and EDX registers is not defined; that is, specific bytes are not designated to contain descriptors for specific cache or TLB types. The descriptors may appear in any order.

</tbody>
</table>
CPUID—CPU Identification (Continued)

The first member of the family of Pentium 4 processors will return the following information about caches and TLBs when the CPUID instruction is executed with an input value of 2:

EAX 66 5B 50 01H
EBX 0H
ECX 0H
EDX 00 7A 70 00H

These values are interpreted as follows:

- The least-significant byte (byte 0) of register EAX is set to 01H, indicating that the CPUID instruction needs to be executed only once with an input value of 2 to retrieve complete information about the processor’s caches and TLBs.

- The most-significant bit of all four registers (EAX, EBX, ECX, and EDX) is set to 0, indicating that each register contains valid 1-byte descriptors.

</tbody>
</table>
CPUID—CPU Identification (Continued)

- Bytes 1, 2, and 3 of register EAX indicate that the processor contains the following:
  - 50H—A 64-entry instruction TLB, for mapping 4-KByte and 2-MByte or 4-MByte pages.
  - 5BH—A 64-entry data TLB, for mapping 4-KByte and 4-MByte pages.
  - 66H—An 8-KByte 1st level data cache, 4-way set associative, with a 64-byte cache line size.

- The descriptors in registers EBX and ECX are valid, but contain null descriptors.

- Bytes 0, 1, 2, and 3 of register EDX indicate that the processor contains the following:
  - 00H—Null descriptor.
  - 70H—A 12-KByte 1st level code cache, 4-way set associative, with a 64-byte cache line size.
  - 7AH—A 256-KByte 2nd level cache, 8-way set associative, with a 128-byte cache line size.
  - 00H—Null descriptor.

Brand Identification

To facilitate brand identification of IA-32 processors with the CPUID instruction, two features are provided: brand index and brand string.

The brand index was added to the CPUID instruction with the Pentium III Xeon processor and will be included on all future IA-32 processors, including the Pentium 4 processors. The brand index provides an entry point into a brand identification table that is maintained in memory by system software and is accessible from system- and user-level code. In this table, each brand index is associated with an ASCII brand identification string that identifies the official Intel family and model number of a processor (for example, “Intel Pentium II processor”).

When executed with a value of 1 in the EAX register, the CPUID instruction returns the brand index to the low byte in EBX. Software can then use this index to locate the brand identification string for the processor in the brand identification table. The first entry (brand index 0) in this table is reserved, allowing for backward compatibility with processors that do not support the brand identification feature. Table 3-11 shows those brand indices that currently have processor brand identification strings associated with them.

It is recommended that (1) all reserved entries included in the brand identification table be associated with a brand string that indicates that the index is reserved for future Intel processors and (2) that software be prepared to handle reserved brand indices gracefully.

<td>Reserved for future processor</td>
</tr>
</tbody>
</table>

Note
† Indicates versions of these processors that were introduced after the Pentium III Xeon processor.

The brand string feature is an extension to the CPUID instruction introduced in the Pentium 4 processors. With this feature, the CPUID instruction returns the ASCII brand identification string and the maximum operating frequency of the processor to the EAX, EBX, ECX, and EDX registers. (Note that the frequency returned is the maximum operating frequency that the processor has been qualified for and not the current operating frequency of the processor.)

To use the brand string feature, the CPUID instructions must be executed three times, once with an input value of 8000002H in the EAX register, and a second time an input value of 80000003H, and a third time with a value of 80000004H.

The brand string is architecturally defined to be 48 byte long: the first 47 bytes contain ASCII characters and the 48th byte is defined to be null (0). The string may be right justified (with leading spaces) for implementation simplicity. For each input value (EAX is 80000002H, 80000003H, or 80000004H), the CPUID instruction returns 16 bytes of the brand string to the EAX, EBX, ECX, and EDX registers. Processor implementations may return less than the 47 ASCII characters, in which case the string will be null terminated and the processor will return valid data for each of the CPUID input values of 80000002H, 80000003H, and 80000004H.

Table 3-12 shows the brand string that is returned by the first processor in the family of Pentium 4 processors.

NOTE

When a frequency is given in a brand string, it is the maximum qualified frequency of the processor, not the actual frequency the processor is running at.
CPUID—CPU Identification (Continued)

The following procedure can be used for detection of the brand string feature:

1. Execute the CPUID instruction with input value in EAX of 80000000H.
2. If (EAX_Return_Value AND (80000000H) ≠ 0) then the processor supports the extended CPUID functions and EAX contains the largest extended function input value supported.
3. If EAX_Return_Value ≥ 80000004H, then the CPUID instruction supports the brand string feature.

</tr>
</tbody>
</table>

To identify an IA-32 processor using the CPUID instruction, brand identification software should use the following brand identification techniques ordered by decreasing priority:

- Processor brand string
- Processor brand index and a software supplied brand string table.
- Table based mechanism using type, family, model, stepping, and cache information returned by the CPUID instruction.

IA-32 Architecture Compatibility

The CPUID instruction is not supported in early models of the Intel486 processor or in any IA-32 processor earlier than the Intel486 processor.

NOTE
In earlier IA-32 processors that do not support the CPUID instruction, execution of the instruction results in an invalid opcode (#UD) exception being generated.
CVTDQ2PD—Convert Packed Doubleword Integers to Packed Double-Precision Floating-Point Values

**Description**
Converts two packed signed doubleword integers in the source operand (second operand) to two packed double-precision floating-point values in the destination operand (first operand). The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. When the source operand is an XMM register, the packed integers are located in the low quadword of the register.

**Operation**
DEST[63-0] ← Convert_Integer_To_Double_Precision_Floating_Point(SRC[31-0]);
DEST[127-64] ← Convert_Integer_To_Double_Precision_Floating_Point(SRC[63-32]);

**Intel C/C++ Compiler Intrinsic Equivalent**
CVTDQ2PD __m128d _mm_cvtepi32_pd(__m128di a)

**SIMD Floating-Point Exceptions**
None.

**Protected Mode Exceptions**

- **#GP(0)** For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
- **#SS(0)** For an illegal address in the SS segment.
- **#PF(fault-code)** For a page fault.
- **#NM** If TS in CR0 is set.
- **#XM** If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

CVTPD2PI—Convert Packed Double-Precision Floating-Point Values to Packed Doubleword Integers

**Description**

Converts two packed double-precision floating-point values from the source operand (second operand) to two packed signed doubleword integers in the destination operand (first operand). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an MMX register.

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the CVTPD2PI instruction is executed.

**Operation**

\[
\text{DEST}[31-0] \leftarrow \text{Convert Double-Precision Floating Point To Integer}(\text{SRC}[63-0]); \\
\text{DEST}[63-32] \leftarrow \text{Convert Double-Precision Floating Point To Integer}(\text{SRC}[127-64]); \\
\]

CVTPS2PI—Convert Packed Single-Precision Floating-Point Values to Packed Doubleword Integers

Description

Converts two packed single-precision floating-point values in the source operand (second operand) to two packed signed doubleword integers in the destination operand (first operand). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an MMX register. When the source operand is an XMM register, the two single-precision floating-point values are contained in the low quadword of the register.

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the CVTPS2PI instruction is executed.

Operation

CVTSD2SI—Convert Scalar Double-Precision Floating-Point Value to Doubleword Integer

**Description**

Converts a double-precision floating-point value in the source operand (second operand) to a signed doubleword integer in the destination operand (first operand). The source operand can be an XMM register or a 64-bit memory location. The destination operand is a general-purpose register. When the source operand is an XMM register, the double-precision floating-point value is contained in the low quadword of the register.

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

**Operation**

\[
\text{DEST}[31:0] \leftarrow \text{Convert\_Double\_Precision\_Floating\_Point\_To\_Integer(SRC[63:0])};
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

CVTTPD2PI—Convert with Truncation Packed Double-Precision Floating-Point Values to Packed Doubleword Integers

**Description**

Converts two packed double-precision floating-point values in the source operand (second operand) to two packed signed doubleword integers in the destination operand (first operand). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an MMX register.

When a conversion is inexact, a truncated (round toward zero) result is returned. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the CVTTPD2PI instruction is executed.

**Operation**

\[
\text{DEST}[31-0] \leftarrow \text{Convert Double Precision Floating Point To Integer Truncate} (\text{SRC}[63-0]); \\

CVTTPS2PI—Convert with Truncation Packed Single-Precision Floating-Point Values to Packed Doubleword Integers

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 2C /r</td>
<td>CVTTPS2PI mm, xmm/m64</td>
<td>Convert two single-precision floating-point values from xmm/m64 to two signed doubleword signed integers in mm using truncation.</td>
</tr>
</tbody>
</table>

Description

Converts two packed single-precision floating-point values in the source operand (second operand) to two packed signed doubleword integers in the destination operand (first operand). The source operand can be an XMM register or a 64-bit memory location. The destination operand is an MMX register. When the source operand is an XMM register, the two single-precision floating-point values are contained in the low quadword of the register.

When a conversion is inexact, a truncated (round toward zero) result is returned. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the CVTTPS2PI instruction is executed.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
**CVTTS2DI—Convert with Truncation Scalar Double-Precision Floating-Point Value to Signed Doubleword Integer**

**Description**
Converts a double-precision floating-point value in the source operand (second operand) to a signed doubleword integer in the destination operand (first operand). The source operand can be an XMM register or a 64-bit memory location. The destination operand is a general-purpose register. When the source operand is an XMM register, the double-precision floating-point value is contained in the low quadword of the register.

When a conversion is inexact, a truncated (round toward zero) result is returned. If a converted result is larger than the maximum signed doubleword integer, the indefinite integer value (80000000H) is returned.

**Operation**
DEST[31-0] ← Convert_Double_Precision_Floating_Point_To_Integer_Truncate(SRC[63-0]);

**Intel C/C++ Compiler Intrinsic Equivalent**
int_mm_cvttsd_si32(__m128d a)

**SIMD Floating-Point Exceptions**

CWD/CDQ—Convert Word to Doubleword/Convert Doubleword to Quadword

Description

Doubles the size of the operand in register AX or EAX (depending on the operand size) by means of sign extension and stores the result in registers DX:AX or EDX:EAX, respectively. The CWD instruction copies the sign (bit 15) of the value in the AX register into every bit position in the DX register (see Figure 7-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume I). The CDQ instruction copies the sign (bit 31) of the value in the EAX register into every bit position in the EDX register.

The CWD instruction can be used to produce a doubleword dividend from a word before a word division, and the CDQ instruction can be used to produce a quadword dividend from a doubleword before doubleword division.

The CWD and CDQ mnemonics reference the same opcode. The CWD instruction is intended for use when the operand-size attribute is 16 and the CDQ instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when CWD is used and to 32 when CDQ is used. Others may treat these mnemonics as synonyms (CWD/CDQ) and use the current setting of the operand-size attribute to determine the size of values to be converted, regardless of the mnemonic used.

Operation

IF OperandSize ← 16 (* CWD instruction *)
    THEN DX ← SignExtend(AX);
    ELSE (* OperandSize ← 32, CDQ instruction *)
        EDX ← SignExtend(EAX);
FI;

Flags Affected

None.

Exceptions (All Operating Modes)

None.
CWDE—Convert Word to Doubleword

See entry for CBW/CWDE—Convert Byte to Word/Convert Word to Doubleword.
DAA—Decimal Adjust AL after Addition

**Description**

Adjusts the sum of two packed BCD values to create a packed BCD result. The AL register is the implied source and destination operand. The DAA instruction is only useful when it follows an ADD instruction that adds (binary addition) two 2-digit, packed BCD values and stores a byte result in the AL register. The DAA instruction then adjusts the contents of the AL register to contain the correct 2-digit, packed BCD result. If a decimal carry is detected, the CF and AF flags are set accordingly.

**Operation**

\[
\text{IF } ((\text{AL AND } 0FH) > 9) \text{ or } AF \leftarrow 1 \text{ THEN}
\]

\[
\begin{align*}
\text{AL} & \leftarrow \text{AL} + 6; \\
\text{CF} & \leftarrow \text{CF OR CarryFromLastAddition}; (* \text{ CF OR carry from } \text{AL} \leftarrow \text{AL} + 6 *) \\
\text{AF} & \leftarrow 1; \\
\text{ELSE} \\
\text{AF} & \leftarrow 0;
\end{align*}
\]

\[
\text{FI;}
\]

\[
\text{IF } ((\text{AL AND } F0H) > 90H) \text{ or } CF \leftarrow 1 \text{ THEN}
\]

\[
\begin{align*}
\text{AL} & \leftarrow \text{AL} + 60H; \\
\text{CF} & \leftarrow 1; \\
\text{ELSE} \\
\text{CF} & \leftarrow 0;
\end{align*}
\]

\[
\text{FI;}
\]

**Example**

DAA—Decimal Adjust AL after Addition (Continued)

Flags Affected

The CF and AF flags are set if the adjustment of the value results in a decimal carry in either digit of the result (see the “Operation” section above). The SF, ZF, and PF flags are set according to the result. The OF flag is undefined.

Exceptions (All Operating Modes)

None.
DAS—Decimal Adjust AL after Subtraction

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2F</td>
<td>DAS</td>
<td>Decimal adjust AL after subtraction</td>
</tr>
</tbody>
</table>

**Description**

Adjusts the result of the subtraction of two packed BCD values to create a packed BCD result. The AL register is the implied source and destination operand. The DAS instruction is only useful when it follows a SUB instruction that subtracts (binary subtraction) one 2-digit, packed BCD value from another and stores a byte result in the AL register. The DAS instruction then adjusts the contents of the AL register to contain the correct 2-digit, packed BCD result. If a decimal borrow is detected, the CF and AF flags are set accordingly.

**Operation**

\[
\text{IF } (\text{AL AND 0FH}) > 9 \text{ OR AF} \leftarrow 1 \text{ THEN} \\
\quad \text{AL} \leftarrow \text{AL} - 6; \\
\quad \text{CF} \leftarrow \text{CF OR BorrowFromLastSubtraction}; (* \text{CF OR borrow from AL} \leftarrow \text{AL} - 6 *) \\
\quad \text{AF} \leftarrow 1; \\
\quad \text{ELSE AF} \leftarrow 0; \\
\text{FI;} \\
\text{IF } ((\text{AL} > 9FH) \text{ or CF} \leftarrow 1) \text{ THEN} \\
\quad \text{AL} \leftarrow \text{AL} - 60H; \\
\quad \text{CF} \leftarrow 1; \\
\quad \text{ELSE CF} \leftarrow 0; \\
\text{FI;} \\
\]

**Example**

Before: AL=35H BL=47H EFLAGS (OSZAPC)=XXXXXX

After: AL=EEH BL=47H EFLAGS (OSZAPC)=010111

DAA

Before: AL=EEH BL=47H EFLAGS (OSZAPC)=010111

After: AL=88H BL=47H EFLAGS (OSZAPC)=X10111

**Flags Affected**

The CF and AF flags are set if the adjustment of the value results in a decimal borrow in either digit of the result (see the “Operation” section above). The SF, ZF, and PF flags are set according to the result. The OF flag is undefined.

**Exceptions (All Operating Modes)**

None.
DEC—Decrement by 1

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>

<td>48+rw</td>
<td>DEC r16</td>
<td>Decrement r16 by 1</td>
</tr>
<tr>
<td>48+rd</td>
<td>DEC r32</td>
<td>Decrement r32 by 1</td>
</tr>
</tbody>
</table>

Description
Subtracts 1 from the destination operand, while preserving the state of the CF flag. The destination operand can be a register or a memory location. This instruction allows a loop counter to be updated without disturbing the CF flag. (To perform a decrement operation that updates the CF flag, use a SUB instruction with an immediate operand of 1.)

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation
DEST ← DEST – 1;

Flags Affected
The CF flag is not affected. The OF, SF, ZF, AF, and PF flags are set according to the result.

Protected Mode Exceptions
#GP(0)    If the destination operand is located in a nonwritable segment.
          If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
          If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0)    If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0)    If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP    If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS    If a memory operand effective address is outside the SS segment limit.
DEC—Decrement by 1 (Continued)

Virtual-8086 Mode Exceptions

#GP(0)  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0)  If a memory operand effective address is outside the SS segment limit.
#PF(fault-code)  If a page fault occurs.
#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
DIV—Unsigned Divide

**Description**
Divides (unsigned) the value in the AX, DX:AX, or EDX:EAX registers (dividend) by the source operand (divisor) and stores the result in the AX (AH:AL), DX:AX, or EDX:EAX registers. The source operand can be a general-purpose register or a memory location. The action of this instruction depends on the operand size (dividend/divisor), as shown in the following table:

<table>
<thead>
<tr>
<th>Operand Size</th>
<th>Dividend</th>
<th>Divisor</th>
<th>Quotient</th>
<th>Remainder</th>
<th>Maximum Quotient</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word/byte</td>
<td>AX</td>
<td>r/m8</td>
<td>AL</td>
<td>AH</td>
<td>255</td>
</tr>
<tr>
<td>Doubleword/word</td>
<td>DX:AX</td>
<td>r/m16</td>
<td>AX</td>
<td>DX</td>
<td>65,535</td>
</tr>
<tr>
<td>Quadword/doubleword</td>
<td>EDX:EAX</td>
<td>r/m32</td>
<td>EAX</td>
<td>EDX</td>
<td>$2^{32} - 1$</td>
</tr>
</tbody>
</table>

Non-integral results are truncated (chopped) towards 0. The remainder is always less than the divisor in magnitude. Overflow is indicated with the #DE (divide error) exception rather than with the CF flag.

**Operation**
IF SRC ← 0
    THEN #DE; (* divide error *)
FI;
IF OpepreadSize ← 8 (* word/byte operation *)
    THEN
        temp ← AX / SRC;

#AC(0)      If alignment checking is enabled and an unaligned memory reference is made.
DIVPD—Divide Packed Double-Precision Floating-Point Values

**Description**

Performs a SIMD divide of the two packed double-precision floating-point values in the destination operand (first operand) by the two packed double-precision floating-point values in the source operand (second operand), and stores the packed double-precision floating-point results in the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 11-3 in the IA-32 Intel Architecture Software Developer's Manual, Volume I for an illustration of a SIMD double-precision floating-point operation.

**Operation**

\[
\begin{align*}
\text{DEST}[63-0] & \leftarrow \text{DEST}[63-0] / (\text{SRC}[63-0]); \\
\text{DEST}[127-64] & \leftarrow \text{DEST}[127-64] / (\text{SRC}[127-64]);
\end{align*}
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

```
DIVPD _m128 _mm_div_pd(_m128 a, _m128 b)
```

**SIMD Floating-Point Exceptions**

Overflow, Underflow, Invalid, Divide-by-Zero, Precision, Denormal.

</table>

**Description**

Divides the low single-precision floating-point value in the destination operand (first operand) by the low single-precision floating-point value in the source operand (second operand), and stores the single-precision floating-point result in the destination operand. The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The three high-order doublewords of the destination operand remain unchanged. See Figure 10-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a scalar single-precision floating-point operation.

**Operation**

DEST[31-0] ← DEST[31-0] / SRC[31-0];
* DEST[127-32] remains unchanged *

**Intel C/C++ Compiler Intrinsic Equivalent**

DIVSS __m128 _mm_div_ss(__m128 a, __m128 b)

**SIMD Floating-Point Exceptions**

Overflow, Underflow, Invalid, Divide-by-Zero, Precision, Denormal.

**Protected Mode Exceptions**

- #GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
- #SS(0) For an illegal address in the SS segment.
- #PF(fault-code) For a page fault.
- #NM If TS in CR0 is set.
- #XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
- #UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
  - If EM in CR0 is set.
  - If OSFXSR in CR4 is 0.
  - If CPUID feature flag SSE is 0.
DIVSS—Divide Scalar Single-Precision Floating-Point Values
(Continued)

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
EMMS—Empty MMX State

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 77</td>
<td>EMMS</td>
<td>Set the x87 FPU tag word to empty.</td>
</tr>
</tbody>
</table>

**Description**

Sets the values of all the tags in the x87 FPU tag word to empty (all 1s). This operation marks the x87 FPU data registers (which are aliased to the MMX registers) as available for use by x87 FPU floating-point instructions. (See Figure 8-7 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for the format of the x87 FPU tag word.) All other MMX instructions (other than the EMMS instruction) set all the tags in x87 FPU tag word to valid (all 0s).

The EMMS instruction must be used to clear the MMX state at the end of all MMX procedures or subroutines and before calling other procedures or subroutines that may execute x87 floating-point instructions. If a floating-point instruction loads one of the registers in the x87 FPU data register stack before the x87 FPU tag word has been reset by the EMMS instruction, an x87 floating-point register stack overflow can occur that will result in an x87 floating-point exception or incorrect result.

**Operation**

\[ x87FPUTagWord \leftarrow \text{FFFFH}; \]

**Intel C/C++ Compiler Intrinsic Equivalent**

`void_mm_empty()`

**Flags Affected**

None.

**Real-Address Mode Exceptions**

Same as for protected mode exceptions.

**Virtual-8086 Mode Exceptions**

Same as for protected mode exceptions.
ENTER—Make Stack Frame for Procedure Parameters

Description

Creates a stack frame for a procedure. The first operand (size operand) specifies the size of the stack frame (that is, the number of bytes of dynamic storage allocated on the stack for the procedure). The second operand (nesting level operand) gives the lexical nesting level (0 to 31) of the procedure. The nesting level determines the number of stack frame pointers that are copied into the “display area” of the new stack frame from the preceding frame. Both of these operands are immediate values.

The stack-size attribute determines whether the BP (16 bits) or EBP (32 bits) register specifies the current frame pointer and whether SP (16 bits) or ESP (32 bits) specifies the stack pointer.

The ENTER and companion LEAVE instructions are provided to support block structured languages. The ENTER instruction (when used) is typically the first instruction in a procedure and is used to set up a new stack frame for a procedure. The LEAVE instruction is then used at the end of the procedure (just before the RET instruction) to release the stack frame.

If the nesting level is 0, the processor pushes the frame pointer from the EBP register onto the stack, copies the current stack pointer from the ESP register into the EBP register, and loads the ESP register with the current stack-pointer value minus the value in the size operand. For nesting levels of 1 or greater, the processor pushes additional frame pointers on the stack before adjusting the stack pointer. These additional frame pointers provide the called procedure with access points to other nested frames on the stack. See “Procedure Calls for Block-Structured Languages” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for more information about the actions of the ENTER instruction.

Operation

NestingLevel ← NestingLevel MOD 32
IF StackSize ← 32
  THEN
    Push(EBP) ;
    FrameTemp ← ESP;
  ELSE (* StackSize ← 16*)
    Push(BP);
    FrameTemp ← SP;
  FI;
IF NestingLevel ← 0
  THEN GOTO CONTINUE;
FI;

Protected Mode Exceptions

#SS(0)  If the new value of the SP or ESP register is outside the stack segment limit.

#PF(fault-code)  If a page fault occurs.

Real-Address Mode Exceptions

#SS(0)  If the new value of the SP or ESP register is outside the stack segment limit.

Virtual-8086 Mode Exceptions

#SS(0)  If the new value of the SP or ESP register is outside the stack segment limit.

#PF(fault-code)  If a page fault occurs.
F2XM1—Compute $2^x - 1$

Opcode

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 F0</td>
<td>F2XM1</td>
<td>Replace ST(0) with $(2^{ST(0)} - 1)$</td>
</tr>
</tbody>
</table>

**Description**

Computes the exponential value of 2 to the power of the source operand minus 1. The source operand is located in register ST(0) and the result is also stored in ST(0). The value of the source operand must lie in the range $-1.0$ to $+1.0$. If the source value is outside this range, the result is undefined.

The following table shows the results obtained when computing the exponential value of various classes of numbers, assuming that neither overflow nor underflow occurs.

<table>
<thead>
<tr>
<th>ST(0) SRC</th>
<th>ST(0) DEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-1.0$ to $-0$</td>
<td>$-0.5$ to $-0$</td>

Real-Address Mode Exceptions
#NM EM or TS in CR0 is set.
FABS—Absolute Value (Continued)

Virtual-8086 Mode Exceptions

#NM EM or TS in CR0 is set.
FADD/FADDP/FIADD—Add

**Description**

Adds the destination and source operands and stores the sum in the destination location. The destination operand is always an FPU register; the source operand can be a register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

The no-operand version of the instruction adds the contents of the ST(0) register to the ST(1) register. The one-operand version adds the contents of a memory location (either a floating-point or an integer value) to the contents of the ST(0) register. The two-operand version adds the contents of the ST(0) register to the ST(i) register or vice versa. The value in ST(0) can be doubled by coding:

```
FADD ST(0), ST(0);
```

The FADDP instructions perform the additional operation of popping the FPU register stack after storing the result. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. (The no-operand version of the floating-point add instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FADD rather than FADDP.)

The FIADD instructions convert an integer source operand to double extended-precision floating-point format before performing the addition.

The table on the following page shows the results obtained when adding various classes of numbers, assuming that neither overflow nor underflow occurs.

When the sum of two operands with opposite signs is 0, the result is +0, except for the round toward $-\infty$ mode, in which case the result is $-0$. When the source operand is an integer 0, it is treated as a +0.

When both operand are infinities of the same sign, the result is $\infty$ of the expected sign. If both operands are infinities of opposite signs, an invalid-operation exception is generated.
FADD/FADDP/FIADD—Add (Continued)

NOTES:
F Means finite floating-point value.
I Means integer.
* Indicates floating-point invalid-arithmetic-operand (#IA) exception.

Operation
IF instruction is FIADD
THEN
    DEST ← DEST + ConvertToDoubleExtendedPrecisionFP(SRC);
ELSE (* source operand is floating-point value *)
    DEST ← DEST + SRC;
FI;
IF instruction ← FADDP
THEN
    PopRegisterStack;
FI;

FPU Flags Affected
C1 Set to 0 if stack underflow occurred.
Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.
C0, C2, C3 Undefined.

Floating-Point Exceptions
#IS Stack underflow occurred.
#IA Operand is an SNaN value or unsupported format.
Operands are infinities of unlike sign.
FADD/FADDP/FIADD—Add (Continued)

#D Source operand is a denormal value.

#U Result is too small for destination format.

#O Result is too large for destination format.

#P Value cannot be represented exactly in destination format.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FBLD—Load Binary Coded Decimal

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF /4</td>
<td>FBLD m80 dec</td>
<td>Convert BCD value to floating-point and push onto the FPU stack.</td>
</tr>
</tbody>
</table>

Description

Converts the BCD source operand into double extended-precision floating-point format and pushes the value onto the FPU stack. The source operand is loaded without rounding errors. The sign of the source operand is preserved, including that of −0.

The packed BCD digits are assumed to be in the range 0 through 9; the instruction does not check for invalid digits (AH through FH). Attempting to load an invalid encoding produces an undefined result.

Operation

\[
\begin{align*}
\text{TOP} & \leftarrow \text{TOP} - 1; \\
\text{ST}(0) & \leftarrow \text{ConvertToDoubleExtendedPrecisionFP}(	ext{SRC});
\end{align*}
\]

FPU Flags Affected

C1 Set to 1 if stack overflow occurred; otherwise, cleared to 0.
C0, C2, C3 Undefined.

Floating-Point Exceptions

#IS Stack overflow occurred.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
FBLD—Load Binary Coded Decimal (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FBSTP—Store BCD Integer and Pop

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF/6</td>
<td>FBSTP m80bcd</td>
<td>Store ST(0) in m80bcd and pop ST(0).</td>
</tr>
</tbody>
</table>

**Description**

Converts the value in the ST(0) register to an 18-digit packed BCD integer, stores the result in the destination operand, and pops the register stack. If the source value is a non-integral value, it is rounded to an integer value, according to rounding mode specified by the RC field of the FPU control word. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1.

The destination operand specifies the address where the first byte destination value is to be stored. The BCD value (including its sign bit) requires 10 bytes of space in memory.

The following table shows the results obtained when storing various classes of numbers in packed BCD format.

<table>
<thead>
<tr>
<th>ST(0)</th>
<th>DEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>−∞</td>
<td>*</td>
</tr>
<tr>
<td>−F &lt; −1</td>
<td>−D</td>
</tr>
<tr>
<td>−1 &lt; −F &lt; −0</td>
<td>**</td>
</tr>
<tr>
<td>−0</td>
<td>−0</td>
</tr>
<tr>
<td>+0</td>
<td>+0</td>
</tr>
<tr>
<td>+0 &lt; +F &lt; +1</td>
<td>**</td>
</tr>
<tr>
<td>+F &gt; +1</td>
<td>+D</td>
</tr>
<tr>
<td>+∞</td>
<td>*</td>
</tr>
<tr>
<td>NaN</td>
<td>*</td>
</tr>
</tbody>
</table>

**NOTES:**

F Means finite floating-point value.
D Means packed-BCD number.
* Indicates floating-point invalid-operation (#IA) exception.
** ±0 or ±1, depending on the rounding mode.

If the source value is too large for the destination format and the invalid-operation exception is not masked, an invalid-operation exception is generated and no value is stored in the destination operand. If the invalid-operation exception is masked, the packed BCD indefinite value is stored in memory.

If the source value is a quiet NaN, an invalid-operation exception is generated. Quiet NaNs do not normally cause this exception to be generated.
FBSTP—Store BCD Integer and Pop (Continued)

Operation
DEST ← BCD(ST(0));
PopRegisterStack;

FPU Flags Affected
C1 Set to 0 if stack underflow occurred.
Indicates rounding direction if the inexact exception (#P) is generated:
0 = not roundup; 1 ← roundup.
C0, C2, C3 Undefined.

Floating-Point Exceptions
#IS Stack underflow occurred.
#IA Source operand is empty; contains a NaN, ±∞, or unsupported format; or
contains value that exceeds 18 BCD digits in length.
#P Value cannot be represented exactly in destination format.

Protected Mode Exceptions
#GP(0) If a segment register is being loaded with a segment selector that points to
a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
FBSTP—Store BCD Integer and Pop (Continued)

Virtual-8086 Mode Exceptions

- **#GP(0)**: If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS(0)**: If a memory operand effective address is outside the SS segment limit.
- **#NM**: EM or TS in CR0 is set.
- **#PF(fault-code)**: If a page fault occurs.
- **#AC(0)**: If alignment checking is enabled and an unaligned memory reference is made.

FCLEX/FNCLEX—Clear Exceptions

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9B DB E2</td>
<td>FCLEX</td>
<td>Clear floating-point exception flags after checking for pending unmasked floating-point exceptions.</td>
</tr>
<tr>
<td>DB E2</td>
<td>FNCLEX*</td>
<td>Clear floating-point exception flags without checking for pending unmasked floating-point exceptions.</td>
</tr>
</tbody>
</table>

NOTE:
* See “IA-32 Architecture Compatibility” below.

Description
Clears the floating-point exception flags (PE, UE, OE, ZE, DE, and IE), the exception summary status flag (ES), the stack fault flag (SF), and the busy flag (B) in the FPU status word. The FCLEX instruction checks for and handles any pending unmasked floating-point exceptions before clearing the exception flags; the FNCLEX instruction does not.

The assembler issues two instructions for the FCLEX instruction (an FWAIT instruction followed by an FNCLEX instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

IA-32 Architecture Compatibility
When operating a Pentium or Intel486 processor in MS-DOS* compatibility mode, it is possible (under unusual circumstances) for an FNCLEX instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of these circumstances. An FNCLEX instruction cannot be interrupted in this way on a Pentium 4 or P6 family processor.

This instruction affects only the x87 FPU floating-point exception flags. It does not affect the SIMD floating-point exception flags in the MXCRS register.

Operation
FPUSStatusWord[0..7] ← 0;
FPUSStatusWord[15] ← 0;

FPU Flags Affected
The PE, UE, OE, ZE, DE, IE, ES, SF, and B flags in the FPU status word are cleared. The C0, C1, C2, and C3 flags are undefined.

Floating-Point Exceptions
None.

</table>

**Description**
Tests the status flags in the EFLAGS register and moves the source operand (second operand) to the destination operand (first operand) if the given test condition is true. The conditions for each mnemonic are given in the Description column above and in Table 7-4 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1. The source operand is always in the ST(i) register and the destination operand is always ST(0).

The FCMOVcc instructions are useful for optimizing small IF constructions. They also help eliminate branching overhead for IF operations and the possibility of branch mispredictions by the processor.

A processor may not support the FCMOVcc instructions. Software can check if the FCMOVcc instructions are supported by checking the processor’s feature information with the CPUID instruction (see “COMISS—Compare Scalar Ordered Single-Precision Floating-Point Values and Set EFLAGS” in this chapter). If both the CMOV and FPU feature bits are set, the FCMOVcc instructions are supported.

**IA-32 Architecture Compatibility**
The FCMOVcc instructions were introduced to the IA-32 Architecture in the Pentium Pro processor family and is not available in earlier IA-32 processors.

**Operation**
IF condition TRUE

\[
\text{ST}(0) \leftarrow \text{ST}(i)
\]
FI;

**FPU Flags Affected**
C1 Set to 0 if stack underflow occurred.
C0, C2, C3 Undefined.
FCMOVcc—Floating-Point Conditional Move (Continued)

Floating-Point Exceptions

#IS Stack underflow occurred.

Integer Flags Affected

None.

Real-Address Mode Exceptions

#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#NM EM or TS in CR0 is set.
FCOM/FCOMP/FCOMPP—Compare Floating Point Values

Description

Compares the contents of register ST(0) and source value and sets condition code flags C0, C2, and C3 in the FPU status word according to the results (see the table below). The source operand can be a data register or a memory location. If no source operand is given, the value in ST(0) is compared with the value in ST(1). The sign of zero is ignored, so that −0.0 ← +0.0.

<table>
<thead>
<tr>
<th>Condition</th>
<th>C3</th>
<th>C2</th>
<th>C0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ST(0) &gt; SRC</td>

</tr>
<tr>
<td>Unordered*</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

NOTE:

* Flags not set if unmasked invalid-arithmetic-operand (#IA) exception is generated.

This instruction checks the class of the numbers being compared (see “FXAM—Examine” in this chapter). If either operand is a NaN or is in an unsupported format, an invalid-arithmetic-operand exception (#IA) is raised and, if the exception is masked, the condition flags are set to “unordered.” If the invalid-arithmetic-operand exception is unmasked, the condition code flags are not set.

The FCOMP instruction pops the register stack following the comparison operation and the FCOMPP instruction pops the register stack twice following the comparison operation. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1.
FCOM/FCOMP/FCOMPP—Compare Floating Point Values
(Continued)

The FCOM instructions perform the same operation as the FUCOM instructions. The only
difference is how they handle QNaN operands. The FCOM instructions raise an invalid-arithmetic-operand exception (#IA) when either or both of the operands is a NaN value or is in an unsupported format. The FUCOM instructions perform the same operation as the FCOM instructions, except that they do not generate an invalid-arithmetic-operand exception for QNaNs.

Operation

CASE (relation of operands) OF
   ST > SRC: C3, C2, C0 ← 000;
   ST < SRC: C3, C2, C0 ← 001;
   ST ← SRC: C3, C2, C0 ← 100;
ESAC;
IF ST(0) or SRC ← NaN or unsupported format
   THEN
      #IA
      IF FPUControlWord.IM ← 1
         THEN

<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

NOTE:
* Flags not set if unmasked invalid-arithmetic-operand (#IA) exception is generated.

The FCOMI/FCOMIP instructions perform the same operation as the FUCOMI/FUCOMIP instructions. The only difference is how they handle QNaN operands. The FCOMI/FCOMIP instructions set the status flags to “unordered” and generate an invalid-arithmetic-operand exception (#IA) when either or both of the operands is a NaN value (SNaN or QNaN) or is in an unsupported format.

The FUCOMI/FUCOMIP instructions perform the same operation as the FCOMI/FCOMIP instructions, except that they do not generate an invalid-arithmetic-operand exception for QNaNs. See “FXAM—Examine” in this chapter for additional information on unordered comparisons.

If invalid-operation exception is unmasked, the status flags are not set if the invalid-arithmetic-operand exception is generated.

The FCOMP and FUCOMP instructions also pop the register stack following the comparison operation. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1.

FCOS—Cosine

Description

Computes the cosine of the source operand in register ST(0) and stores the result in ST(0). The source operand must be given in radians and must be within the range $-2^{63}$ to $+2^{63}$. The following table shows the results obtained when taking the cosine of various classes of numbers, assuming that neither overflow nor underflow occurs.

<table>
<thead>
<tr>
<th>ST(0) SRC</th>
<th>ST(0) DEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-\infty$</td>
<td>NaN</td>
</tr>
<tr>
<td>$-F$</td>
<td>$-1$ to $+1$</td>
</tr>
<tr>
<td>$-0$</td>
<td>$+1$</td>
</tr>
<tr>
<td>$+0$</td>
<td>$+1$</td>
</tr>
<tr>
<td>$+F$</td>
<td>$-1$ to $+1$</td>
</tr>
<tr>
<td>$+\infty$</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

NOTES:
F Means finite floating-point value.
* Indicates floating-point invalid-arithmetic-operand (#IA) exception.

If the source operand is outside the acceptable range, the C2 flag in the FPU status word is set, and the value in register ST(0) remains unchanged. The instruction does not raise an exception when the source operand is out of range. It is up to the program to check the C2 flag for out-of-range conditions. Source values outside the range $-2^{63}$ to $+2^{63}$ can be reduced to the range of the instruction by subtracting an appropriate integer multiple of $2\pi$ or by using the FPREM instruction with a divisor of $2\pi$. See the section titled “Pi” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a discussion of the proper value to use for $\pi$ in performing such reductions.

Operation

IF $|\text{ST}(0)| < 2^{63}$
THEN
   \[ C2 \leftarrow 0; \]
   \[ \text{ST}(0) \leftarrow \text{cosine}(\text{ST}(0)); \]
ELSE (*source operand is out-of-range *)
   \[ C2 \leftarrow 1; \]
FI;
FCOS—Cosine (Continued)

FPU Flags Affected

C1  Set to 0 if stack underflow occurred.
Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.
Undefined if C2 is 1.

C2  Set to 1 if source operand is outside the range $-2^{63}$ to $+2^{63}$; otherwise, cleared to 0.

C0, C3 Undefined.

Floating-Point Exceptions

#IS  Stack underflow occurred.
#IA  Source operand is an SNaN value, ∞, or unsupported format.
#D   Result is a denormal value.
#U   Result is too small for destination format.
#P   Value cannot be represented exactly in destination format.

Protected Mode Exceptions

#NM  EM or TS in CR0 is set.

Real-Address Mode Exceptions

#NM  EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#NM  EM or TS in CR0 is set.
FDECSTP—Decrement Stack-Top Pointer

Description
Subtracts one from the TOP field of the FPU status word (decrements the top-of-stack pointer). If the TOP field contains a 0, it is set to 7. The effect of this instruction is to rotate the stack by one position. The contents of the FPU data registers and tag register are not affected.

Operation
IF TOP ← 0
   THEN TOP ← 7;
   ELSE TOP ← TOP – 1;
FI;

FPU Flags Affected
The C1 flag is set to 0; otherwise, cleared to 0. The C0, C2, and C3 flags are undefined.

Floating-Point Exceptions
None.

Protected Mode Exceptions
#NM EM or TS in CR0 is set.

Real-Address Mode Exceptions
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions
#NM EM or TS in CR0 is set.

</tr>
</tbody>
</table>

**Description**

Divides the destination operand by the source operand and stores the result in the destination location. The destination operand (dividend) is always in an FPU register; the source operand (divisor) can be a register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

The no-operand version of the instruction divides the contents of the ST(1) register by the contents of the ST(0) register. The one-operand version divides the contents of the ST(0) register by the contents of a memory location (either a floating-point or an integer value). The two-operand version, divides the contents of the ST(0) register by the contents of the ST(i) register or vice versa.

The FDIVP instructions perform the additional operation of popping the FPU register stack after storing the result. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The no-operand version of the floating-point divide instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FDIV rather than FDIVP.

The FIDIV instructions convert an integer source operand to double extended-precision floating-point format before performing the division. When the source operand is an integer 0, it is treated as a +0.

If an unmasked divide-by-zero exception (#Z) is generated, no result is stored; if the exception is masked, an ∞ of the appropriate sign is stored in the destination operand.

The following table shows the results obtained when dividing various classes of numbers, assuming that neither overflow nor underflow occurs.
FDIV/FDIVP/FIDIV—Divide (Continued)

</tr>
</tbody>
</table>

**Description**

Divides the source operand by the destination operand and stores the result in the destination location. The destination operand (divisor) is always in an FPU register; the source operand (dividend) can be a register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

These instructions perform the reverse operations of the FDIV, FDIVP, and FIDIV instructions. They are provided to support more efficient coding.

The no-operand version of the instruction divides the contents of the ST(0) register by the contents of the ST(1) register. The one-operand version divides the contents of a memory location (either a floating-point or an integer value) by the contents of the ST(0) register. The two-operand version, divides the contents of the ST(i) register by the contents of the ST(0) register or vice versa.

The FDIVRP instructions perform the additional operation of popping the FPU register stack after storing the result. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The no-operand version of the floating-point divide instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FDIVR rather than FDIVRP.

The FIDIVR instructions convert an integer source operand to double extended-precision floating-point format before performing the division.

If an unmasked divide-by-zero exception (#Z) is generated, no result is stored; if the exception is masked, an ∞ of the appropriate sign is stored in the destination operand.

The following table shows the results obtained when dividing various classes of numbers, assuming that neither overflow nor underflow occurs.
FDIVR/FDIVRP/FIDIVR—Reverse Divide (Continued)

### Notes:
- **F** Means finite floating-point value.
- **I** Means integer.
- * Indicates floating-point invalid-arithmetic-operand (#IA) exception.
- ** Indicates floating-point zero-divide (#Z) exception.

When the source operand is an integer 0, it is treated as a +0.

#IA Operand is an SNaN value or unsupported format.
   ±∞ / ±∞; ±0 / ±0
#D Result is a denormal value.
#Z SRC / ±0, where SRC is not equal to ±0.
#U Result is too small for destination format.
#O Result is too large for destination format.
#P Value cannot be represented exactly in destination format.

Protected Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
   If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
FDIVR/FDIVRP/FIDIVR—Reverse Divide (Continued)

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
**FFREE—Free Floating-Point Register**

**Description**
Sets the tag in the FPU tag register associated with register ST(i) to empty (11B). The contents of ST(i) and the FPU stack-top pointer (TOP) are not affected.

**Operation**
TAG(i) ← 11B;

**FPU Flags Affected**
C0, C1, C2, C3 undefined.

**Floating-Point Exceptions**
None.

**Protected Mode Exceptions**
#NM EM or TS in CR0 is set.

**Real-Address Mode Exceptions**
#NM EM or TS in CR0 is set.

**Virtual-8086 Mode Exceptions**
#NM EM or TS in CR0 is set.

</table>
FICOM/FICOMP—Compare Integer

Description

Compares the value in ST(0) with an integer source operand and sets the condition code flags C0, C2, and C3 in the FPU status word according to the results (see table below). The integer value is converted to double extended-precision floating-point format before the comparison is made.

<table>
<thead>
<tr>
<th>Condition</th>
<th>C3</th>
<th>C2</th>
<th>C0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ST(0) &gt; SRC</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ST(0) &lt; SRC</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>ST(0) ← SRC</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Unordered</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

These instructions perform an “unordered comparison.” An unordered comparison also checks the class of the numbers being compared (see “FXAM—Examine” in this chapter). If either operand is a NaN or is in an undefined format, the condition flags are set to “unordered.” The sign of zero is ignored, so that –0.0 ← +0.0.

The FICOMP instructions pop the register stack following the comparison. To pop the register stack, the processor marks the ST(0) register empty and increments the stack pointer (TOP) by 1.

Operation

CASE (relation of operands) OF
   ST(0) > SRC: C3, C2, C0 ← 000;
   ST(0) < SRC: C3, C2, C0 ← 001;
   ST(0) ← SRC: C3, C2, C0 ← 100;
   Unordered: C3, C2, C0 ← 111;
ESAC;

IF instruction ← FICOMP
   THEN
      PopRegisterStack;
   FI;
FICOM/FICOMP—Compare Integer (Continued)

FPU Flags Affected

C1 Set to 0 if stack underflow occurred; otherwise, set to 0.
C0, C2, C3 See table on previous page.

Floating-Point Exceptions

#IS Stack underflow occurred.
#IA One or both operands are NaN values or have unsupported formats.
#D One or both operands are denormal values.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

</tr>
<tr>
<td>DF /5</td>
<td>FILD m64int</td>
<td>Push m64int onto the FPU register stack.</td>
</tr>
</tbody>
</table>

Description

Converts the signed-integer source operand into double extended-precision floating-point format and pushes the value onto the FPU register stack. The source operand can be a word, doubleword, or quadword integer. It is loaded without rounding errors. The sign of the source operand is preserved.

Operation

\[
\text{TOP} \leftarrow \text{TOP} - 1; \\
\text{ST}(0) \leftarrow \text{ConvertToDoubleExtendedPrecisionFP}(	ext{SRC});
\]

FPU Flags Affected

- C1 Set to 1 if stack overflow occurred; cleared to 0 otherwise.
- C0, C2, C3 Undefined.

Floating-Point Exceptions

- #IS Stack overflow occurred.

Protected Mode Exceptions

- #GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  If the DS, ES, FS, or GS register contains a null segment selector.
- #SS(0) If a memory operand effective address is outside the SS segment limit.
- #NM EM or TS in CR0 is set.
- #PF(fault-code) If a page fault occurs.
- #AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

#GP  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS  If a memory operand effective address is outside the SS segment limit.
#NM  EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0)  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0)  If a memory operand effective address is outside the SS segment limit.
#NM  EM or TS in CR0 is set.
#PF(fault-code)  If a page fault occurs.
#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
FINCSTP—Increment Stack-Top Pointer

Description
Adds one to the TOP field of the FPU status word (increments the top-of-stack pointer). If the TOP field contains a 7, it is set to 0. The effect of this instruction is to rotate the stack by one position. The contents of the FPU data registers and tag register are not affected. This operation is not equivalent to popping the stack, because the tag for the previous top-of-stack register is not marked empty.

Operation
IF TOP ← 7
THEN TOP ← 0;
ELSE TOP ← TOP + 1;
FI;

FPU Flags Affected
The C1 flag is set to 0; otherwise, cleared to 0. The C0, C2, and C3 flags are undefined.

Floating-Point Exceptions
None.

Protected Mode Exceptions
#NM EM or TS in CR0 is set.

Real-Address Mode Exceptions
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions
#NM EM or TS in CR0 is set.

FINIT/FNINIT—Initialize Floating-Point Unit

### Opcode Instruction Description

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9B DB E3</td>
<td>FINIT</td>
<td>Initialize FPU after checking for pending unmasked floating-point exceptions.</td>
</tr>
<tr>
<td>DB E3</td>
<td>FNINIT*</td>
<td>Initialize FPU without checking for pending unmasked floating-point exceptions.</td>
</tr>
</tbody>
</table>

**NOTE:**
* See “IA-32 Architecture Compatibility” below.

**Description**

Sets the FPU control, status, tag, instruction pointer, and data pointer registers to their default states. The FPU control word is set to 037FH (round to nearest, all exceptions masked, 64-bit precision). The status word is cleared (no exception flags set, TOP is set to 0). The data registers in the register stack are left unchanged, but they are all tagged as empty (11B). Both the instruction and data pointers are cleared.

The FINIT instruction checks for and handles any pending unmasked floating-point exceptions before performing the initialization; the FNINIT instruction does not.

The assembler issues two instructions for the FINIT instruction (an FWAIT instruction followed by an FNINIT instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

**IA-32 Architecture Compatibility**

When operating a Pentium or Intel486 processor in MS-DOS compatibility mode, it is possible (under unusual circumstances) for an FNINIT instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for a description of these circumstances. An FNINIT instruction cannot be interrupted in this way on a Pentium Pro processor.

In the Intel387 math coprocessor, the FINIT/FNINIT instruction does not clear the instruction and data pointers.

This instruction affects only the x87 FPU. It does not affect the XMM and MXCSR registers.

**Operation**

```
FPUControlWord ← 037FH;
FPUStatusWord ← 0;
FPUTagWord ← FFFFH;
FPUDataPointer ← 0;
FPUInstructionPointer ← 0;
FPULastInstructionOpcode ← 0;
```

3-235
FPU Flags Affected
C0, C1, C2, C3 cleared to 0.

Floating-Point Exceptions
None.

Protected Mode Exceptions
#NM Em or TS in CR0 is set.

Real-Address Mode Exceptions
#NM Em or TS in CR0 is set.

Virtual-8086 Mode Exceptions
#NM Em or TS in CR0 is set.
FIST/FISTP—Store Integer

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF /2</td>
<td>FIST m16int</td>
<td>Store ST(0) in m16int</td>
</tr>
<tr>
<td>DB /2</td>
<td>FIST m32int</td>
<td>Store ST(0) in m32int</td>

<td>Store ST(0) in m16int and pop register stack</td>
</tr>
<tr>
<td>DB /3</td>
<td>FISTP m32int</td>
<td>Store ST(0) in m32int and pop register stack</td>
</tr>
<tr>
<td>DF /7</td>
<td>FISTP m64int</td>
<td>Store ST(0) in m64int and pop register stack</td>
</tr>
</tbody>
</table>

Description

The FIST instruction converts the value in the ST(0) register to a signed integer and stores the result in the destination operand. Values can be stored in word or doubleword integer format. The destination operand specifies the address where the first byte of the destination value is to be stored.

The FISTP instruction performs the same operation as the FIST instruction and then pops the register stack. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The FISTP instruction can also store values in quad-word-integer format.

The following table shows the results obtained when storing various classes of numbers in integer format.

<table>
<thead>
<tr>
<th>ST(0)</th>
<th>DEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>−∞</td>
<td>*</td>
</tr>
<tr>
<td>−F &lt; −1</td>
<td>−I</td>
</tr>
<tr>
<td>−1 &lt; −F &lt; −0</td>
<td>**</td>
</tr>
<tr>
<td>−0</td>
<td>0</td>
</tr>
<tr>
<td>+0</td>
<td>0</td>
</tr>
<tr>
<td>+0 &lt; +F &lt; +1</td>
<td>**</td>
</tr>
<tr>
<td>+F &gt; +1</td>
<td>+I</td>
</tr>
<tr>
<td>+∞</td>
<td>*</td>
</tr>
<tr>
<td>NaN</td>
<td>*</td>
</tr>
</tbody>
</table>

NOTES:

F Means finite floating-point value.
I Means integer.
* Indicates floating-point invalid-operation (#IA) exception.
** 0 or ±1, depending on the rounding mode.
FIST/FISTP—Store Integer (Continued)

If the source value is a non-integral value, it is rounded to an integer value, according to the rounding mode specified by the RC field of the FPU control word.

If the value being stored is too large for the destination format, is an \( \infty \), is a NaN, or is in an unsupported format and if the invalid-arithmetic-operand exception (#IA) is unmasked, an invalid-operation exception is generated and no value is stored in the destination operand. If the invalid-operation exception is masked, the integer indefinite value is stored in the destination operand.

Operation

\[
\text{DEST} \leftarrow \text{Integer(ST(0))}; \\
\text{IF instruction} \leftarrow \text{FISTP} \\
\text{THEN} \\
\quad \text{PopRegisterStack}; \\
\text{FI};
\]

FPU Flags Affected

C1 Set to 0 if stack underflow occurred.

Indicates rounding direction if the inexact exception (#P) is generated:

\[ 0 \leftarrow \text{not roundup}; 1 \leftarrow \text{roundup}. \]

Cleared to 0 otherwise.

C0, C2, C3 Undefined.

Floating-Point Exceptions

#IS Stack underflow occurred.

#IA Source operand is too large for the destination format

Source operand is a NaN value or unsupported format.

#P Value cannot be represented exactly in destination format.

Protected Mode Exceptions

#GP(0) If the destination is located in a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.
FIST/FISTP—Store Integer (Continued)

#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

<td>FLD m80fp</td>
<td>Push m80fp onto the FPU register stack.</td>
</tr>
<tr>
<td>D9 C0+i</td>
<td>FLD ST(i)</td>
<td>Push ST(i) onto the FPU register stack.</td>
</tr>
</tbody>
</table>

Description

Pushes the source operand onto the FPU register stack. The source operand can be in single-precision, double-precision, or double extended-precision floating-point format. If the source operand is in single-precision or double-precision floating-point format, it is automatically converted to the double extended-precision floating-point format before being pushed on the stack.

The FLD instruction can also push the value in a selected FPU register [ST(i)] onto the stack. Here, pushing register ST(0) duplicates the stack top.

Operation

IF SRC is ST(i)
THEN
   temp ← ST(i)
FI;
TOP ← TOP − 1;
IF SRC is memory-operand
THEN
   ST(0) ← ConvertToDoubleExtendedPrecisionFP(SRC);
ELSE (* SRC is ST(i) *)
   ST(0) ← temp;
FI;

FPU Flags Affected

C1 Set to 1 if stack overflow occurred; otherwise, cleared to 0.
C0, C2, C3 Undefined.

Floating-Point Exceptions

#IS Stack overflow occurred.
#IA Source operand is a SNan value or unsupported format.
#D Source operand is a denormal value. Does not occur if the source operand is in double extended-precision floating-point format.
FLD—Load Floating Point Value (Continued)

Protected Mode Exceptions

#GP(0) If destination is located in a nonwritable segment.
    If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
    If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FLD1/FLDL2T/FLDL2E/FLDPI/FLDLG2/FLDLN2/FLDZ—Load Constant

<table>
<thead>
<tr>

<td>Push log₁₀e onto the FPU register stack.</td>
</tr>
<tr>
<td>D9 EE</td>
<td>FLDZ</td>
<td>Push +0.0 onto the FPU register stack.</td>
</tr>
</tbody>
</table>

Description

Push one of seven commonly used constants (in double extended-precision floating-point format) onto the FPU register stack. The constants that can be loaded with these instructions include +1.0, +0.0, log₂10, log₂e, π, log₁₀₂, and log₁₀e. For each constant, an internal 66-bit constant is rounded (as specified by the RC field in the FPU control word) to double extended-precision floating-point format. The inexact-result exception (#P) is not generated as a result of the rounding.

See the section titled “Pi” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of the π constant.

Operation

TOP ← TOP – 1;
ST(0) ← CONSTANT;

FPU Flags Affected

C1 Set to 1 if stack overflow occurred; otherwise, cleared to 0.
C0, C2, C3 Undefined.

Floating-Point Exceptions

#IS Stack overflow occurred.

Protected Mode Exceptions

#NM EM or TS in CR0 is set.

Real-Address Mode Exceptions

#NM EM or TS in CR0 is set.
FLD1/FLDL2T/FLDL2E/FLDPI/FLDLG2/FLDLN2/FLDZ—Load Constant (Continued)

Virtual-8086 Mode Exceptions

#NM  EM or TS in CR0 is set.

IA-32 Architecture Compatibility

When the RC field is set to round-to-nearest, the FPU produces the same constants that is produced by the Intel 8087 and Intel 287 math coprocessors.
FLDCW—Load x87 FPU Control Word

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 /5</td>
<td>FLDCW m2byte</td>
<td>Load FPU control word from m2byte.</td>
</tr>
</tbody>
</table>

Description

Loads the 16-bit source operand into the FPU control word. The source operand is a memory location. This instruction is typically used to establish or change the FPU’s mode of operation.

If one or more exception flags are set in the FPU status word prior to loading a new FPU control word and the new control word unmasks one or more of those exceptions, a floating-point exception will be generated upon execution of the next floating-point instruction (except for the no-wait floating-point instructions, see the section titled “Software Exception Handling” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). To avoid raising exceptions when changing FPU operating modes, clear any pending exceptions (using the FCLEX or FNCLEX instruction) before loading the new control word.

Operation

FPUControlWord ← SRC;

FPU Flags Affected

C0, C1, C2, C3 undefined.

Floating-Point Exceptions

None; however, this operation might unmask a pending exception in the FPU status word. That exception is then generated upon execution of the next “waiting” floating-point instruction.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
    If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
FLDCW—Load x87 FPU Control Word (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
INSTRUCTION SET REFERENCE

FLDENV—Load x87 FPU Environment

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 /4</td>
<td>FLDENV m14/28byte</td>
<td>Load FPU environment from m14byte or m28byte.</td>
</tr>
</tbody>
</table>

**Description**

Loads the complete x87 FPU operating environment from memory into the FPU registers. The source operand specifies the first byte of the operating-environment data in memory. This data is typically written to the specified memory location by a FSTENV or FNSTENV instruction.

The FPU operating environment consists of the FPU control word, status word, tag word, instruction pointer, data pointer, and last opcode. Figures 8-9 through 8-12 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, show the layout in memory of the loaded environment, depending on the operating mode of the processor (protected or real) and the current operand-size attribute (16-bit or 32-bit). In virtual-8086 mode, the real mode layouts are used.

The FLDENV instruction should be executed in the same operating mode as the corresponding FSTENV/FNSTENV instruction.

If one or more unmasked exception flags are set in the new FPU status word, a floating-point exception will be generated upon execution of the next floating-point instruction (except for the no-wait floating-point instructions, see the section titled “Software Exception Handling” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). To avoid generating exceptions when loading a new environment, clear all the exception flags in the FPU status word that is being loaded.

**Operation**

FPUCtrlWord ← SRC(FPUCtrlWord);
FPUStrWord ← SRC(FPUStrWord);
FPUTagWord ← SRC(FPUTagWord);
FPUDataPointer ← SRC(FPUDataPointer);
FPUI指令Pointer ← SRC(FPUI指令Pointer);
FPULastInstructionOpcode ← SRC(FPULastInstructionOpcode);

**FPU Flags Affected**

The C0, C1, C2, C3 flags are loaded.

**Floating-Point Exceptions**

None; however, if an unmasked exception is loaded in the status word, it is generated upon execution of the next "waiting" floating-point instruction.
INSTRUCTION SET REFERENCE

</table>

Description

Multiplies the destination and source operands and stores the product in the destination location. The destination operand is always an FPU data register; the source operand can be an FPU data register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

The no-operand version of the instruction multiplies the contents of the ST(1) register by the contents of the ST(0) register and stores the product in the ST(1) register. The one-operand version multiplies the contents of the ST(0) register by the contents of a memory location (either a floating point or an integer value) and stores the product in the ST(0) register. The two-operand version, multiplies the contents of the ST(0) register by the contents of the ST(i) register, or vice versa, with the result being stored in the register specified with the first operand (the destination operand).

The FMULP instructions perform the additional operation of popping the FPU register stack after storing the product. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The no-operand version of the floating-point multiply instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FMUL rather than FMULP.

The FIMUL instructions convert an integer source operand to double extended-precision floating-point format before performing the multiplication.

The sign of the result is always the exclusive-OR of the source signs, even if one or more of the values being multiplied is 0 or \( \infty \). When the source operand is an integer 0, it is treated as a +0.

The following table shows the results obtained when multiplying various classes of numbers, assuming that neither overflow nor underflow occurs.

INSTRUCTION SET REFERENCE

FPATAN—Partial Arctangent

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 F3</td>
<td>FPATAN</td>
<td>Replace ST(1) with arctan(ST(1)/ST(0)) and pop the register stack</td>
</tr>
</tbody>
</table>

Description

Computes the arctangent of the source operand in register ST(1) divided by the source operand in register ST(0), stores the result in ST(1), and pops the FPU register stack. The result in register ST(0) has the same sign as the source operand ST(1) and a magnitude less than $+\pi$.

The FPATAN instruction returns the angle between the X axis and the line from the origin to the point (X,Y), where Y (the ordinate) is ST(1) and X (the abscissa) is ST(0). The angle depends on the sign of X and Y independently, not just on the sign of the ratio Y/X. This is because a point (−X,Y) is in the second quadrant, resulting in an angle between $\pi/2$ and $\pi$, while a point (X,−Y) is in the fourth quadrant, resulting in an angle between 0 and $−\pi/2$. A point (−X,−Y) is in the third quadrant, giving an angle between $−\pi/2$ and $−\pi$.

The following table shows the results obtained when computing the arctangent of various classes of numbers, assuming that underflow does not occur.

</tbody>
</table>

NOTES:

F Means finite floating-point value.

* Table 8-10 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, specifies that the ratios 0/0 and $\infty/\infty$ generate the floating-point invalid arithmetic-operation exception and, if this exception is masked, the floating-point QNaN indefinite value is returned. With the FPATAN instruction, the 0/0 or $\infty/\infty$ value is actually not calculated using division. Instead, the arctangent of the two variables is derived from a standard mathematical formulation that is generalized to allow complex numbers as arguments. In this complex variable formulation, arctangent(0,0) etc. has well defined values. These values are needed to develop a library to compute transcendental functions with complex arguments, based on the FPU functions that only allow floating-point values as arguments.

There is no restriction on the range of source operands that FPATAN can accept.
FPATAN—Partial Arctangent (Continued)

IA-32 Architecture Compatibility
The source operands for this instruction are restricted for the 80287 math coprocessor to the following range:

\[ 0 \leq |ST(1)| < |ST(0)| < +\infty \]

Operation
ST(1) ← \text{arctan}(ST(1) / ST(0));
PopRegisterStack;

FPU Flags Affected
C1 Set to 0 if stack underflow occurred.
Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not round; 1 ← round.
C0, C2, C3 Undefined.

Floating-Point Exceptions
#IS Stack underflow occurred.
#IA Source operand is an SNaN value or unsupported format.
#D Source operand is a denormal value.
#U Result is too small for destination format.
#P Value cannot be represented exactly in destination format.

Protected Mode Exceptions
#NM EM or TS in CR0 is set.

Real-Address Mode Exceptions
#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions
#NM EM or TS in CR0 is set.
FPREM—Partial Remainder

Description

Computes the remainder obtained from dividing the value in the ST(0) register (the dividend) by the value in the ST(1) register (the divisor or modulus), and stores the result in ST(0). The remainder represents the following value:

\[ \text{Remainder} \leftarrow ST(0) - (Q \times ST(1)) \]

Here, \( Q \) is an integer value that is obtained by truncating the floating-point number quotient of \[ ST(0) / ST(1) \] toward zero. The sign of the remainder is the same as the sign of the dividend. The magnitude of the remainder is less than that of the modulus, unless a partial remainder was computed (as described below).

This instruction produces an exact result; the inexact-result exception does not occur and the rounding control has no effect. The following table shows the results obtained when computing the remainder of various classes of numbers, assuming that underflow does not occur.

</tr>
</tbody>
</table>

NOTES:

- \( F \) Means finite floating-point value.
- * Indicates floating-point invalid-arithmetic-operand (#IA) exception.
- ** Indicates floating-point zero-divide (#Z) exception.

When the result is 0, its sign is the same as that of the dividend. When the modulus is \( \infty \), the result is equal to the value in ST(0).

The FPREM instruction does not compute the remainder specified in IEEE Std 754. The IEEE specified remainder can be computed with the FPREM1 instruction. The FPREM instruction is provided for compatibility with the Intel 8087 and Intel287 math coprocessors.
FPREM—Partial Remainder (Continued)

The FPREM instruction gets its name “partial remainder” because of the way it computes the remainder. This instruction arrives at a remainder through iterative subtraction. It can, however, reduce the exponent of ST(0) by no more than 63 in one execution of the instruction. If the instruction succeeds in producing a remainder that is less than the modulus, the operation is complete and the C2 flag in the FPU status word is cleared. Otherwise, C2 is set, and the result in ST(0) is called the partial remainder. The exponent of the partial remainder will be less than the exponent of the original dividend by at least 32. Software can re-execute the instruction (using the partial remainder in ST(0) as the dividend) until C2 is cleared. (Note that while executing such a remainder-computation loop, a higher-priority interrupting routine that needs the FPU can force a context switch in-between the instructions in the loop.)

An important use of the FPREM instruction is to reduce the arguments of periodic functions. When reduction is complete, the instruction stores the three least-significant bits of the quotient in the C3, C1, and C0 flags of the FPU status word. This information is important in argument reduction for the tangent function (using a modulus of $\pi/4$), because it locates the original angle in the correct one of eight sectors of the unit circle.

**Operation**

\[
D \leftarrow \text{exponent}(\text{ST}(0)) - \text{exponent}(\text{ST}(1));
\]

\[
\text{IF } D < 64 \text{ THEN}
\]

\[
Q \leftarrow \text{Integer(TruncateToZero(} \text{ST}(0) / \text{ST}(1))\text{)};
\]

\[
\text{ST}(0) \leftarrow \text{ST}(0) - (\text{ST}(1) \times Q);
\]

\[
C2 \leftarrow 0;
\]

\[
C0, C3, C1 \leftarrow \text{LeastSignificantBits}(Q); (* Q2, Q1, Q0 *)
\]

\[
\text{ELSE}
\]

\[
C2 \leftarrow 1;
\]

\[
N \leftarrow \text{an implementation-dependent number between 32 and 63};
\]

\[
QQ \leftarrow \text{Integer(TruncateToZero(} \text{(} \text{ST}(0) / \text{ST}(1)) / 2^{(D - N)}\text{)}\text{)};
\]

\[
\text{ST}(0) \leftarrow \text{ST}(0) - (\text{ST}(1) \times QQ \times 2^{(D - N)});
\]

\[
\text{FI;}
\]

**FPU Flags Affected**

- **C0** Set to bit 2 (Q2) of the quotient.
- **C1** Set to 0 if stack underflow occurred; otherwise, set to least significant bit of quotient (Q0).
- **C2** Set to 0 if reduction complete; set to 1 if incomplete.
- **C3** Set to bit 1 (Q1) of the quotient.

**Floating-Point Exceptions**

- **#IS** Stack underflow occurred.
FPREM—Partial Remainder (Continued)

#IA Source operand is an SNaN value, modulus is 0, dividend is $\infty$, or unsupported format.

#D Source operand is a denormal value.

#NM EM or TS in CR0 is set.
FPREM1—Partial Remainder

**Description**

Computes the IEEE remainder obtained from dividing the value in the ST(0) register (the dividend) by the value in the ST(1) register (the divisor or modulus), and stores the result in ST(0). The remainder represents the following value:

\[ \text{Remainder} \leftarrow \text{ST}(0) - (Q \times \text{ST}(1)) \]

where \( Q \) is an integer value that is obtained by rounding the floating-point number quotient of \([\text{ST}(0) / \text{ST}(1)]\) toward the nearest integer value. The magnitude of the remainder is less than or equal to half the magnitude of the modulus, unless a partial remainder was computed (as described below).

This instruction produces an exact result; the precision (inexact) exception does not occur and the rounding control has no effect. The following table shows the results obtained when computing the remainder of various classes of numbers, assuming that underflow does not occur.

</tr>
</tbody>
</table>

**NOTES:**

F Means finite floating-point value.

* Indicates floating-point invalid-arithmetic-operand (#IA) exception.

** Indicates floating-point zero-divide (#Z) exception.

When the result is 0, its sign is the same as that of the dividend. When the modulus is --∞, the result is equal to the value in ST(0).
The FPREM1 instruction computes the remainder specified in IEEE Standard 754. This instruction operates differently from the FPREM instruction in the way that it rounds the quotient of ST(0) divided by ST(1) to an integer (see the “Operation” section below).

Like the FPREM instruction, the FPREM1 computes the remainder through iterative subtraction, but can reduce the exponent of ST(0) by no more than 63 in one execution of the instruction. If the instruction succeeds in producing a remainder that is less than one half the modulus, the operation is complete and the C2 flag in the FPU status word is cleared. Otherwise, C2 is set, and the result in ST(0) is called the **partial remainder**. The exponent of the partial remainder will be less than the exponent of the original dividend by at least 32. Software can re-execute the instruction (using the partial remainder in ST(0) as the dividend) until C2 is cleared. (Note that while executing such a remainder-computation loop, a higher-priority interrupting routine that needs the FPU can force a context switch in-between the instructions in the loop.)

An important use of the FPREM1 instruction is to reduce the arguments of periodic functions. When reduction is complete, the instruction stores the three least-significant bits of the quotient in the C3, C1, and C0 flags of the FPU status word. This information is important in argument reduction for the tangent function (using a modulus of π/4), because it locates the original angle in the correct one of eight sectors of the unit circle.

**Operation**

\[
D \leftarrow \text{exponent}(\text{ST}(0)) - \text{exponent}(\text{ST}(1)) ; \\
\text{IF } D < 64 \text{ THEN} \\
\quad Q \leftarrow \text{Integer} (\text{RoundTowardNearestInteger} (\text{ST}(0) / \text{ST}(1))) ; \\
\quad \text{ST}(0) \leftarrow \text{ST}(0) - (\text{ST}(1) \times Q) ; \\
\quad C2 \leftarrow 0 ; \\
\quad C0, C3, C1 \leftarrow \text{LeastSignificantBits}(Q); (* Q2, Q1, Q0 *) \\
\text{ELSE} \\
\quad C2 \leftarrow 1 ; \\
\quad N \leftarrow \text{an implementation-dependent number between 32 and 63} ; \\
\quad QQ \leftarrow \text{Integer} (\text{TruncateTowardZero} ((\text{ST}(0) / \text{ST}(1)) / 2^{D - N})) ; \\
\quad \text{ST}(0) \leftarrow \text{ST}(0) - (\text{ST}(1) \times QQ \times 2^{D - N}) ; \\
\text{FI} ;
\]

**FPU Flags Affected**

- **C0**: Set to 2 (Q2) of the quotient.
- **C1**: Set to 0 if stack underflow occurred; otherwise, set to least significant bit of quotient (Q0).
- **C2**: Set to 0 if reduction complete; set to 1 if incomplete.
- **C3**: Set to 1 (Q1) of the quotient.
FPREM1—Partial Remainder (Continued)

Floating-Point Exceptions

FPTAN—Partial Tangent

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Clocks</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 F2</td>
<td>FPTAN</td>
<td>17-173</td>
<td>Replace ST(0) with its tangent and push 1 onto the FPU stack.</td>
</tr>
</tbody>
</table>

**Description**

Computes the tangent of the source operand in register ST(0), stores the result in ST(0), and pushes a 1.0 onto the FPU register stack. The source operand must be given in radians and must be less than ±263. The following table shows the unmasked results obtained when computing the partial tangent of various classes of numbers, assuming that underflow does not occur.

<table>
<thead>
<tr>
<th>ST(0) SRC</th>
<th>ST(0) DEST</th>
</tr>
</thead>
<tbody>
<tr>
<td>−∞</td>
<td>*</td>
</tr>
<tr>

</tr>
<tr>
<td>+F</td>
<td>−F to +F</td>
</tr>
<tr>
<td>+∞</td>
<td>*</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**NOTES:**

F Means finite floating-point value.

* Indicates floating-point invalid-arithmetic-operand (#IA) exception.

If the source operand is outside the acceptable range, the C2 flag in the FPU status word is set, and the value in register ST(0) remains unchanged. The instruction does not raise an exception when the source operand is out of range. It is up to the program to check the C2 flag for out-of-range conditions. Source values outside the range −263 to +263 can be reduced to the range of the instruction by subtracting an appropriate integer multiple of 2π or by using the FPREM instruction with a divisor of 2π. See the section titled “Pi” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a discussion of the proper value to use for π in performing such reductions.

The value 1.0 is pushed onto the register stack after the tangent has been computed to maintain compatibility with the Intel 8087 and Intel287 math coprocessors. This operation also simplifies the calculation of other trigonometric functions. For instance, the cotangent (which is the reciprocal of the tangent) can be computed by executing a FDIVR instruction after the FPTAN instruction.
FPTAN—Partial Tangent (Continued)

**Operation**

IF ST(0) < $2^{63}$
THEN
  C2 ← 0;
  ST(0) ← tan(ST(0));
  TOP ← TOP − 1;
  ST(0) ← 1.0;
ELSE (*source operand is out-of-range *)
  C2 ← 1;
FI;

**FPU Flags Affected**

C1 Set to 0 if stack underflow occurred; set to 1 if stack overflow occurred.
Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.

C2 Set to 1 if source operand is outside the range $-2^{63}$ to $+2^{63}$; otherwise, cleared to 0.

C0, C3 Undefined.

**Floating-Point Exceptions**

#IS Stack underflow occurred.
#IA Source operand is an SNaN value, $\infty$, or unsupported format.
#D Source operand is a denormal value.
#U Result is too small for destination format.
#P Value cannot be represented exactly in destination format.

FRNDINT—Round to Integer

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D0 FC</td>
<td>FRNDINT</td>
<td>Round ST(0) to an integer.</td>
</tr>
</tbody>
</table>

**Description**

Rounds the source value in the ST(0) register to the nearest integral value, depending on the current rounding mode (setting of the RC field of the FPU control word), and stores the result in ST(0).

If the source value is ∞, the value is not changed. If the source value is not an integral value, the floating-point inexact-result exception (#P) is generated.

**Operation**

\[
\text{ST}(0) \leftarrow \text{RoundToIntegralValue}(\text{ST}(0));
\]

**FPU Flags Affected**

- **C1**: Set to 0 if stack underflow occurred.
  Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.
- **C0, C2, C3**: Undefined.

**Floating-Point Exceptions**

- **#IS**: Stack underflow occurred.
- **#IA**: Source operand is an SNaN value or unsupported format.
- **#D**: Source operand is a denormal value.
- **#P**: Source operand is not an integral value.

**Real-Address Mode Exceptions**

- **#NM**: EM or TS in CR0 is set.

**Virtual-8086 Mode Exceptions**

- **#NM**: EM or TS in CR0 is set.
FRSTOR—Restore x87 FPU State

**Description**

Loads the FPU state (operating environment and register stack) from the memory area specified with the source operand. This state data is typically written to the specified memory location by a previous FSAVE/FNSAVE instruction.

The FPU operating environment consists of the FPU control word, status word, tag word, instruction pointer, data pointer, and last opcode. Figures 8-9 through 8-12 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, show the layout in memory of the stored environment, depending on the operating mode of the processor (protected or real) and the current operand-size attribute (16-bit or 32-bit). In virtual-8086 mode, the real mode layouts are used. The contents of the FPU register stack are stored in the 80 bytes immediately follow the operating environment image.

The FRSTOR instruction should be executed in the same operating mode as the corresponding FSAVE/FNSAVE instruction.

If one or more unmasked exception bits are set in the new FPU status word, a floating-point exception will be generated. To avoid raising exceptions when loading a new operating environment, clear all the exception flags in the FPU status word that is being loaded.

**Operation**

\[
\begin{align*}
\text{FPUC} & \leftarrow \text{SRC}[\text{FPUC}] \\
\text{FPUS} & \leftarrow \text{SRC}[\text{FPUS}] \\
\text{FPUT} & \leftarrow \text{SRC}[\text{FPUT}] \\
\text{FPUD} & \leftarrow \text{SRC}[\text{FPUD}] \\
\text{FPUI} & \leftarrow \text{SRC}[\text{FPUI}] \\
\text{FPUO} & \leftarrow \text{SRC}[\text{FPUO}] \\
\text{ST}(0) & \leftarrow \text{SRC}[\text{ST}(0)] \\
\text{ST}(1) & \leftarrow \text{SRC}[\text{ST}(1)] \\
\text{ST}(2) & \leftarrow \text{SRC}[\text{ST}(2)] \\
\text{ST}(3) & \leftarrow \text{SRC}[\text{ST}(3)] \\
\text{ST}(4) & \leftarrow \text{SRC}[\text{ST}(4)] \\
\text{ST}(5) & \leftarrow \text{SRC}[\text{ST}(5)] \\
\text{ST}(6) & \leftarrow \text{SRC}[\text{ST}(6)] \\
\text{ST}(7) & \leftarrow \text{SRC}[\text{ST}(7)]
\end{align*}
\]

**FPU Flags Affected**

The C0, C1, C2, C3 flags are loaded.
FRSTOR—Restore x87 FPU State (Continued)

Floating-Point Exceptions
None; however, this operation might unmask an existing exception that has been detected but not generated, because it was masked. Here, the exception is generated at the completion of the instruction.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FSAVE/FNSAVE—Store x87 FPU State

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9B DD /6</td>
<td>FSAVE m94/108byte</td>

<tr>
<td>DD /6</td>
<td>FNSAVE* m94/108byte</td>
<td>Store FPU environment to m94byte or m108byte without checking for pending unmasked floating-point exceptions. Then re-initialize the FPU.</td>
</tr>
</tbody>
</table>

**NOTE:**
* See “IA-32 Architecture Compatibility” below.

**Description**
Stores the current FPU state (operating environment and register stack) at the specified destination in memory, and then re-initializes the FPU. The FSAVE instruction checks for and handles pending unmasked floating-point exceptions before storing the FPU state; the FNSAVE instruction does not.

The FPU operating environment consists of the FPU control word, status word, tag word, instruction pointer, data pointer, and last opcode. Figures 8-9 through 8-12 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, show the layout in memory of the stored environment, depending on the operating mode of the processor (protected or real) and the current operand-size attribute (16-bit or 32-bit). In virtual-8086 mode, the real mode layouts are used. The contents of the FPU register stack are stored in the 80 bytes immediately follow the operating environment image.

The saved image reflects the state of the FPU after all floating-point instructions preceding the FSAVE/FNSAVE instruction in the instruction stream have been executed.

After the FPU state has been saved, the FPU is reset to the same default values it is set to with the FINIT/FNINIT instructions (see “FINIT/FNINIT—Initialize Floating-Point Unit” in this chapter).

The FSAVE/FNSAVE instructions are typically used when the operating system needs to perform a context switch, an exception handler needs to use the FPU, or an application program needs to pass a “clean” FPU to a procedure.

The assembler issues two instructions for the FSAVE instruction (an FWAIT instruction followed by an FNSAVE instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

**IA-32 Architecture Compatibility**
For Intel math coprocessors and FPU prior to the Intel Pentium processor, an FWAIT instruction should be executed before attempting to read from the memory image stored with a prior FSAVE/FNSAVE instruction. This FWAIT instruction helps insure that the storage operation has been completed.
FSAVE/FNSAVE—Store x87 FPU State (Continued)

When operating a Pentium or Intel 486 processor in MS-DOS compatibility mode, it is possible (under unusual circumstances) for an FNSAVE instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of these circumstances. An FNSAVE instruction cannot be interrupted in this way on a Pentium Pro processor.

Operation

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FScale—Scale

**Description**

Multiplies the destination operand by 2 to the power of the source operand and stores the result in the destination operand. The destination operand is a floating-point value that is located in register ST(0). The source operand is the nearest integer value that is smaller than the value in the ST(1) register (that is, the value in register ST(1) is truncated toward 0 to its nearest integer value to form the source operand). This instruction provides rapid multiplication or division by integral powers of 2 because it is implemented by simply adding an integer value (the source operand) to the exponent of the value in register ST(0). The following table shows the results obtained when scaling various classes of numbers, assuming that neither overflow nor underflow occurs.

<table>
<thead>
<tr>
<th>ST(0)</th>
<th>ST(1)</th>

</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**NOTES:**

F Means finite floating-point value.
N Means integer.

In most cases, only the exponent is changed and the mantissa (significand) remains unchanged. However, when the value being scaled in ST(0) is a denormal value, the mantissa is also changed and the result may turn out to be a normalized number. Similarly, if overflow or underflow results from a scale operation, the resulting mantissa will differ from the source’s mantissa.

The FScale instruction can also be used to reverse the action of the FXtract instruction, as shown in the following example:

```
FXTRACT;
FScale;
FStp ST(1);
```
FSSCALE—Scale (Continued)

In this example, the FXTRACT instruction extracts the significand and exponent from the value in ST(0) and stores them in ST(0) and ST(1) respectively. The FSSCALE then scales the significand in ST(0) by the exponent in ST(1), recreating the original value before the FXTRACT operation was performed. The FSTP ST(1) instruction overwrites the exponent (extracted by the FXTRACT instruction) with the recreated value, which returns the stack to its original state with only one register [ST(0)] occupied.

Operation

\[
\text{ST}(0) \leftarrow \text{ST}(0) \times 2^{\text{ST}(1)};
\]

FPU Flags Affected

C1  Set to 0 if stack underflow occurred.
    Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.

C0, C2, C3  Undefined.

Floating-Point Exceptions

#IS  Stack underflow occurred.

#IA  Source operand is an SNaN value or unsupported format.

#D  Source operand is a denormal value.

#U  Result is too small for destination format.

#O  Result is too large for destination format.

#P  Value cannot be represented exactly in destination format.

Protected Mode Exceptions

#NM  EM or TS in CR0 is set.

Real-Address Mode Exceptions

#NM  EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#NM  EM or TS in CR0 is set.
FSIN—Sine

Description

Computes the sine of the source operand in register ST(0) and stores the result in ST(0). The source operand must be given in radians and must be within the range $-2^{63}$ to $+2^{63}$. The following table shows the results obtained when taking the sine of various classes of numbers, assuming that underflow does not occur.

<table>
<thead>
<tr>
<th>SRC (ST(0))</th>
<th>DEST (ST(0))</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-\infty$</td>
<td>*</td>
</tr>
<tr>

<tr>
<td>$+F$</td>
<td>$-1$ to $+1$</td>
</tr>
<tr>
<td>$+\infty$</td>
<td>*</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

NOTES:

F Means finite floating-point value.
* Indicates floating-point invalid-arithmetic-operand (#IA) exception.

If the source operand is outside the acceptable range, the C2 flag in the FPU status word is set, and the value in register ST(0) remains unchanged. The instruction does not raise an exception when the source operand is out of range. It is up to the program to check the C2 flag for out-of-range conditions. Source values outside the range $-2^{63}$ to $+2^{63}$ can be reduced to the range of the instruction by subtracting an appropriate integer multiple of $2\pi$ or by using the FPREM instruction with a divisor of $2\pi$. See the section titled “Pi” in Chapter 8 of the IA-32 Intel Architecture Software Developer's Manual, Volume 1, for a discussion of the proper value to use for $\pi$ in performing such reductions.

Operation

IF ST(0) < $2^{63}$
THEN
    C2 ← 0;
    ST(0) ← sin(ST(0));
ELSE (* source operand out of range *)
    C2 ← 1;

FST/FSTP—Store Floating Point Value

**Description**

The FST instruction copies the value in the ST(0) register to the destination operand, which can be a memory location or another register in the FPU register stack. When storing the value in memory, the value is converted to single-precision or double-precision floating-point format.

The FSTP instruction performs the same operation as the FST instruction and then pops the register stack. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The FSTP instruction can also store values in memory in double extended-precision floating-point format.

If the destination operand is a memory location, the operand specifies the address where the first byte of the destination value is to be stored. If the destination operand is a register, the operand specifies a register in the register stack relative to the top of the stack.

If the destination size is single-precision or double-precision, the significand of the value being stored is rounded to the width of the destination (according to rounding mode specified by the RC field of the FPU control word), and the exponent is converted to the width and bias of the destination format. If the value being stored is too large for the destination format, a numeric overflow exception (#O) is generated and, if the exception is unmasked, no value is stored in the destination operand. If the value being stored is a denormal value, the denormal exception (#D) is not generated. This condition is simply signaled as a numeric underflow exception (#U) condition.

If the value being stored is ±0, ±∞, or a NaN, the least-significant bits of the significand and the exponent are truncated to fit the destination format. This operation preserves the value’s identity as a 0, ∞, or NaN.

If the destination operand is a non-empty register, the invalid-operation exception is not generated.

**Operation**

```plaintext
DEST ← ST(0);
IF instruction ← FSTP
    THEN
        PopRegisterStack; FI;
```

<tr>
<td>D9 /7</td>
<td>FNSTCW* m2byte</td>
<td>Store FPU control word to m2byte without checking for pending unmasked floating-point exceptions.</td>
</tr>
</tbody>
</table>

NOTE:
* See “IA-32 Architecture Compatibility” below.

Description
Stores the current value of the FPU control word at the specified destination in memory. The FSTCW instruction checks for and handles pending unmasked floating-point exceptions before storing the control word; the FNSTCW instruction does not.

The assembler issues two instructions for the FSTCW instruction (an FWAIT instruction followed by an FNSTCW instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

IA-32 Architecture Compatibility
When operating a Pentium or Intel486 processor in MS-DOS compatibility mode, it is possible (under unusual circumstances) for an FNSTCW instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of these circumstances. An FNSTCW instruction cannot be interrupted in this way on a Pentium Pro processor.

Operation
DEST ← FPUCtrlWord;

FPU Flags Affected
The C0, C1, C2, and C3 flags are undefined.

Floating-Point Exceptions
None.

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FSTENV/FNSTENV—Store x87 FPU Environment

### Description
Saves the current FPU operating environment at the memory location specified with the destination operand, and then masks all floating-point exceptions. The FPU operating environment consists of the FPU control word, status word, tag word, instruction pointer, data pointer, and last opcode. Figures 8-9 through 8-12 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, show the layout in memory of the stored environment, depending on the operating mode of the processor (protected or real) and the current operand-size attribute (16-bit or 32-bit). In virtual-8086 mode, the real mode layouts are used.

The FSTENV instruction checks for and handles any pending unmasked floating-point exceptions before storing the FPU environment; the FNSTENV instruction does not. The saved image reflects the state of the FPU after all floating-point instructions preceding the FSTENV/FNSTENV instruction in the instruction stream have been executed.

These instructions are often used by exception handlers because they provide access to the FPU instruction and data pointers. The environment is typically saved in the stack. Masking all exceptions after saving the environment prevents floating-point exceptions from interrupting the exception handler.

The assembler issues two instructions for the FSTENV instruction (an FWAIT instruction followed by an FNSTENV instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

### IA-32 Architecture Compatibility
When operating a Pentium or Intel486 processor in MS-DOS compatibility mode, it is possible (under unusual circumstances) for an FNSTENV instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for a description of these circumstances. An FNSTENV instruction cannot be interrupted in this way on a Pentium Pro processor.
FSTENV/FNSTENV—Store x87 FPU Environment (Continued)

Operation
DEST[FPUControlWord) ← FPUControlWord;
DEST[FPUStatusWord) ← FPUStatusWord;
DEST[FPUTagWord) ← FPUTagWord;
DEST[FPUDataPointer) ← FPUDataPointer;
DEST[FPUInstructionPointer) ← FPUInstructionPointer;
DEST[FPULastInstructionOpcode) ← FPULastInstructionOpcode;

FPU Flags Affected
The C0, C1, C2, and C3 are undefined.

Floating-Point Exceptions
None.

Protected Mode Exceptions
#GP(0) If the destination is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains
a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is
made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or
GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.
#NM EM or TS in CR0 is set.
Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM EM or TS in CR0 is set.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FSTSW/FNSTSW—Store x87 FPU Status Word

**Description**
Stores the current value of the x87 FPU status word in the destination location. The destination operand can be either a two-byte memory location or the AX register. The FSTSW instruction checks for and handles pending unmasked floating-point exceptions before storing the status word; the FNSTSW instruction does not.

The FNSTSW AX form of the instruction is used primarily in conditional branching (for instance, after an FPU comparison instruction or an FPREM, FPREM1, or FXAM instruction), where the direction of the branch depends on the state of the FPU condition code flags. (See the section titled “Branching and Conditional Moves on FPU Condition Codes” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1.) This instruction can also be used to invoke exception handlers (by examining the exception flags) in environments that do not use interrupts. When the FNSTSW AX instruction is executed, the AX register is updated before the processor executes any further instructions. The status stored in the AX register is thus guaranteed to be from the completion of the prior FPU instruction.

The assembler issues two instructions for the FSTSW instruction (an FWAIT instruction followed by an FNSTSW instruction), and the processor executes each of these instructions in separately. If an exception is generated for either of these instructions, the save EIP points to the instruction that caused the exception.

**IA-32 Architecture Compatibility**
When operating a Pentium or Intel486 processor in MS-DOS compatibility mode, it is possible (under unusual circumstances) for an FNSTSW instruction to be interrupted prior to being executed to handle a pending FPU exception. See the section titled “No-Wait FPU Instructions Can Get FPU Interrupt in Window” in Appendix D of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of these circumstances. An FNSTSW instruction cannot be interrupted in this way on a Pentium 4 or P6 family processor.

Description

Subtracts the source operand from the destination operand and stores the difference in the destination location. The destination operand is always an FPU data register; the source operand can be a register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

The no-operand version of the instruction subtracts the contents of the ST(0) register from the ST(1) register and stores the result in ST(1). The one-operand version subtracts the contents of a memory location (either a floating-point or an integer value) from the contents of the ST(0) register and stores the result in ST(0). The two-operand version, subtracts the contents of the ST(0) register from the ST(i) register or vice versa.

The FSUBP instructions perform the additional operation of popping the FPU register stack following the subtraction. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The no-operand version of the floating-point subtract instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FSUB rather than FSUBP.

The FISUB instructions convert an integer source operand to double extended-precision floating-point format before performing the subtraction.

The following table shows the results obtained when subtracting various classes of numbers from one another, assuming that neither overflow nor underflow occurs. Here, the SRC value is subtracted from the DEST value (DEST − SRC ← result).

When the difference between two operands of like sign is 0, the result is +0, except for the round toward −∞ mode, in which case the result is −0. This instruction also guarantees that +0 − (−0) ← +0, and that −0 − (+0) ← −0. When the source operand is an integer 0, it is treated as a +0.

When one operand is ∞, the result is ∞ of the expected sign. If both operands are ∞ of the same sign, an invalid-operation exception is generated.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
FSUBR/FSUBRP/FISUBR—Reverse Subtract

### Description

Subtracts the destination operand from the source operand and stores the difference in the destination location. The destination operand is always an FPU register; the source operand can be a register or a memory location. Source operands in memory can be in single-precision or double-precision floating-point format or in word or doubleword integer format.

These instructions perform the reverse operations of the FSUB, FSUBP, and FISUB instructions. They are provided to support more efficient coding.

The no-operand version of the instruction subtracts the contents of the ST(1) register from the ST(0) register and stores the result in ST(1). The one-operand version subtracts the contents of the ST(0) register from the contents of a memory location (either a floating-point or an integer value) and stores the result in ST(0). The two-operand version, subtracts the contents of the ST(i) register from the ST(0) register or vice versa.

The FSUBRP instructions perform the additional operation of popping the FPU register stack following the subtraction. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1. The no-operand version of the floating-point reverse subtract instructions always results in the register stack being popped. In some assemblers, the mnemonic for this instruction is FSUBR rather than FSUBRP.

The FISUBR instructions convert an integer source operand to double extended-precision floating-point format before performing the subtraction.

The following table shows the results obtained when subtracting various classes of numbers from one another, assuming that neither overflow nor underflow occurs. Here, the DEST value is subtracted from the SRC value (SRC – DEST ← result).

When the difference between two operands of like sign is 0, the result is +0, except for the round toward −∞ mode, in which case the result is −0. This instruction also guarantees that +0 − (−0) ← +0, and that −0 − (+0) ← −0. When the source operand is an integer 0, it is treated as a +0.

When one operand is ±∞, the result is of the expected sign. If both operands are ±∞ of the same sign, an invalid-operation exception is generated.

</tr>
</tbody>
</table>

NOTE:

* Flags not set if unmasked invalid-arithmetic-operand (#IA) exception is generated.

An unordered comparison checks the class of the numbers being compared (see “FXAM—Examine” in this chapter). The FUCOM instructions perform the same operations as the FCOM instructions. The only difference is that the FUCOM instructions raise the invalid-arithmetic-oprand exception (#IA) only when either or both operands are an SNaN or are in an unsupported format; QNaNs cause the condition code flags to be set to unordered, but do not cause an exception to be generated. The FCOM instructions raise an invalid-operation exception when either or both of the operands are a NaN value of any kind or are in an unsupported format.

As with the FCOM instructions, if the operation results in an invalid-arithmetic-oprand exception being raised, the condition code flags are set only if the exception is masked.

The FUCOMP instruction pops the register stack following the comparison operation and the FUCOMPP instruction pops the register stack twice following the comparison operation. To pop the register stack, the processor marks the ST(0) register as empty and increments the stack pointer (TOP) by 1.

<td>FXCH ST(i)</td>
<td>Exchange the contents of ST(0) and ST(i)</td>
</tr>
<tr>
<td>D9 C9</td>
<td>FXCH</td>
<td>Exchange the contents of ST(0) and ST(1)</td>
</tr>
</tbody>
</table>

**Description**

Exchanges the contents of registers ST(0) and ST(i). If no source operand is specified, the contents of ST(0) and ST(1) are exchanged.

This instruction provides a simple means of moving values in the FPU register stack to the top of the stack [ST(0)], so that they can be operated on by those floating-point instructions that can only operate on values in ST(0). For example, the following instruction sequence takes the square root of the third register from the top of the register stack:

```
FXCH ST(3);
FSQRT;
FXCH ST(3);
```

**Operation**

IF number-of-operands is 1

THEN

- `temp ← ST(0);`
- `ST(0) ← SRC;`
- `SRC ← temp;`

ELSE

- `temp ← ST(0);`
- `ST(0) ← ST(1);`
- `ST(1) ← temp;`

**FPU Flags Affected**

C1 Set to 0 if stack underflow occurred; otherwise, cleared to 0.

C0, C2, C3 Undefined.

**Floating-Point Exceptions**

#IS Stack underflow occurred.

**Protected Mode Exceptions**

#NM EM or TS in CR0 is set.
INSTRUCTION SET REFERENCE

FXCH—Exchange Register Contents (Continued)

Real-Address Mode Exceptions

#NM  EM or TS in CR0 is set.

Virtual-8086 Mode Exceptions

#NM  EM or TS in CR0 is set.
FXRSTOR—Restore x87 FPU, MMX, SSE, and SSE2 State

Description

Reloads the x87 FPU, MMX, XMM, and MXCSR registers from the 512-byte memory image specified in the source operand. This data should have been written to memory previously using the FXSAVE instruction, and the first byte of the data should be located on a 16-byte boundary. Table 3-13 shows the layout of the state information in memory and describes the fields in the memory image for the FXRSTOR and FXSAVE instructions.

The state image referenced with an FXRSTOR instruction must have been saved using an FXSAVE instruction or be in the same format as that shown in Table 3-13. Referencing a state image saved with an FSAVE or FNSAVE instruction will result in an incorrect state restoration.

The FXRSTOR instruction does not flush pending x87 FPU exceptions. To check and raise exceptions when loading x87 FPU state information with the FXRSTOR instruction, use an FWAIT instruction after the FXRSTOR instruction.

If the OSFXSR bit in control register CR4 is not set, the FXRSTOR instruction may not restore the states of the XMM and MXCSR registers. This behavior is implementation dependent.

If the MXCSR state contains an unmasked exception with a corresponding status flag also set, loading the register with the FXRSTOR instruction will not result in a SIMD floating-point error condition being generated. Only the next occurrence of this unmasked exception will result in the exception being generated.

Bit 6 and bits 16 through 32 of the MXCSR register are defined as reserved and should be set to 0. Attempting to write a 1 in any of these bits from the saved state image will result in a general protection exception (#GP) being generated.

Operation

(x87 FPU, MMX, XMM7-XMM0, MXCSR) ← Load(SRC);

x87 FPU and SIMD Floating-Point Exceptions

None.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.

If memory operand is not aligned on a 16-byte boundary, regardless of segment. (See alignment check exception [#AC] below.)
FXRSTOR—Restore x87 FPU, MMX, SSE, and SSE2 State (Continued)

- **#SS(0)** For an illegal address in the SS segment.
- **#PF(fault-code)** For a page fault.
- **#NM** If TS in CR0 is set.
- **#UD** If EM in CR0 is set.

  If CPUID feature flag FXSR is 0.

  If instruction is preceded by a LOCK prefix.

  **#AC** If this exception is disabled a general protection exception (#GP) is signaled if the memory operand is not aligned on a 16-byte boundary, as described above. If the alignment check exception (#AC) is enabled (and the CPL is 3), signaling of #AC is not guaranteed and may vary with implementation, as follows. In all implementations where #AC is not signaled, a general protection exception is signaled in its place. In addition, the width of the alignment check may also vary with implementation. For instance, for a given implementation, an alignment check exception might be signaled for a 2-byte misalignment, whereas a general protection exception might be signaled for all other misalignments (4-, 8-, or 16-byte misalignments).

**Real-Address Mode Exceptions**

- **#GP(0)** If memory operand is not aligned on a 16-byte boundary, regardless of segment.
- **Interrupt 13** If any part of the operand lies outside the effective address space from 0 to FFFFH.
- **#NM** If TS in CR0 is set.
- **#UD** If EM in CR0 is set.

  If CPUID feature flag SSE2 is 0.

  If instruction is preceded by a LOCK override prefix.

**Virtual-8086 Mode Exceptions**

Same exceptions as in Real Address Mode

- **#PF(fault-code)** For a page fault.
- **#AC** For unaligned memory reference if the current privilege level is 3.
FXSAVE—Save x87 FPU, MMX, SSE, and SSE2 State

**Description**

Saves the current state of the x87 FPU, MMX, XMM, and MXCSR registers to a 512-byte memory location specified in the destination operand. Table 3-13 shows the layout of the state information in memory.

**Table 3-13. Layout of FXSAVE and FXRSTOR Memory Region**

0F AE /0 FXSAVE m512byte

Save the x87 FPU, MMX, XMM, and MXCSR register state to m512byte.
FXSAVE—Save x87 FPU, MMX, SSE, and SSE2 State (Continued)

The destination operand contains the first byte of the memory image, and it must be aligned on a 16-byte boundary. A misaligned destination operand will result in a general-protection (#GP) exception being generated (or in some cases, an alignment check exception [#AC]).

The FXSAVE instruction is used when an operating system needs to perform a context switch or when an exception handler needs to save and examine the current state of the x87 FPU, MMX, and/or XMM and MXCSR registers.

The fields in Table 3-13 are as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCW</td>
<td>x87 FPU Control Word (16 bits). See Figure 8-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for the layout of the x87 FPU control word.</td>
</tr>
<tr>
<td>FSW</td>
<td>x87 FPU Status Word (16 bits). See Figure 8-4 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for the layout of the x87 FPU status word.</td>
</tr>
<tr>
<td>FTW</td>
<td>x87 FPU Tag Word (8 bits). The tag information saved here is abridged, as described in the following paragraphs. See Figure 8-7 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for the layout of the x87 FPU tag word.</td>
</tr>
<tr>
<td>FOP</td>
<td>x87 FPU Opcode (16 bits). The lower 11 bits of this field contain the opcode, upper 5 bits are reserved. See Figure 8-8 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for the layout of the x87 FPU opcode field.</td>
</tr>
</tbody>
</table>
| FPU IP| x87 FPU Instruction Pointer Offset (32 bits). The contents of this field differ depending on the current addressing mode (32-bit or 16-bit) of the processor when the FXSAVE instruction was executed:  
  - 32-bit mode—32-bit IP offset.  
  - 16-bit mode—low 16 bits are IP offset; high 16 bits are reserved. See “x87 FPU Instruction and Operand (Data) Pointers” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for a description of the x87 FPU instruction pointer. |
| CS    | x87 FPU Instruction Pointer Selector (16 bits). |
**FXSAVE—Save x87 FPU, MMX, SSE, and SSE2 State (Continued)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| FPU DP | x87 FPU Instruction Operand (Data) Pointer Offset (32 bits). The contents of this field differ depending on the current addressing mode (32-bit or 16-bit) of the processor when the FXSAVE instruction was executed:  
  - 32-bit mode—32-bit IP offset.  
  - 16-bit mode—low 16 bits are IP offset; high 16 bits are reserved.  
  See “x87 FPU Instruction and Operand (Data) Pointers” in Chapter 8 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for a description of the x87 FPU operand pointer. |
| DS    | x87 FPU Instruction Operand (Data) Pointer Selector (16 bits). |
| MXCSR | MXCSR Register State (32 bits). See Figure 10-3 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for the layout of the MXCSR register. If the OSFXSR bit in control register CR4 is not set, the FXSAVE instruction may not save this register. This behavior is implementation dependent. |
| MXCSR_MASK | MXCSR_MASK (32 bits). This value can be used to adjust a value to be written to the MXCSR register to ensure that all reserved bits are set to 0. Setting the reserved bits to 0 prevents a general-protection exception (#GP) from being generated when writing to the MXCSR register with an FXRSTOR or LDMXCSR instruction. See “Guidelines for Writing to the MXCSR Register” in Chapter 11 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for instructions for how to determine and use the MXCSR_MASK value. |
| ST0/MM0 through ST7/MM7 | x87 FPU or MMX registers. These 80-bit fields contain the x87 FPU data registers or the MMX registers, depending on the state of the processor prior to the execution of the FXSAVE instruction. If the processor had been executing x87 FPU instructions prior to the FXSAVE instruction, the x87 FPU data registers are saved; if it had been executing MMX instructions (or SSE or SSE2 instructions that operated on the MMX registers), the MMX registers are saved. When the MMX registers are saved, the high 16-bits of the field are reserved. |
| XMM0 through XMM7 | XMM registers (128 bits per field). If the OSFXSR bit in control register CR4 is not set, the FXSAVE instruction may not save these registers. This behavior is implementation dependent. |
The FXSAVE instruction saves an abridged version of the x87 FPU tag word in the FTW field (unlike the FSAVE instruction, which saves the complete tag word). The tag information is saved in physical register order (R0 through R7), rather than in top-of-stack (TOS) order. With the FXSAVE instruction, however, only a single bit (1 for valid or 0 for empty) is saved for each tag. For example, assume that the tag word is currently set as follows:

\[
\begin{array}{cccccccc}
R7 & R6 & R5 & R4 & R3 & R2 & R1 & R0 \\
11 & xx & xx & xx & 11 & 11 & 11 & 11 \\
\end{array}
\]

Here, 11B indicates empty stack elements and “xx” indicates valid (00B), zero (01B), or special (10B).

For this example, the FXSAVE instruction saves only the following 8-bits of information:

\[
\begin{array}{cccccccc}
R7 & R6 & R5 & R4 & R3 & R2 & R1 & R0 \\
0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\
\end{array}
\]

Here, a 1 is saved for any valid, zero, or special tag, and a 0 is saved for any empty tag.

The operation of the FXSAVE instruction differs from that of the FSAVE instruction, as follows:

- FXSAVE instruction does not check for pending unmasked floating-point exceptions. (The FXSAVE operation in this regard is similar to the operation of the FNSAVE instruction).

- After the FXSAVE instruction has saved the state of the x87 FPU, MMX, XMM, and MXCSR registers, the processor retains the contents of the registers. Because of this behavior, the FXSAVE instruction cannot be used by an application program to pass a “clean” x87 FPU state to a procedure, since it retains the current state. To clean the x87 FPU state, an application must explicitly execute an FINIT instruction after an FXSAVE instruction to reinitialize the x87 FPU state.

- The format of the memory image saved with the FXSAVE instruction is the same regardless of the current addressing mode (32-bit or 16-bit) and operating mode (protected, real address, or system management). This behavior differs from the FSAVE instructions, where the memory image format is different depending on the addressing mode and operating mode. Because of the different image formats, the memory image saved with the FXSAVE instruction cannot be restored correctly with the FRSTOR instruction, and likewise the state saved with the FSAVE instruction cannot be restored correctly with the FXRSTOR instruction.

Note that The FSAVE format for FTW can be recreated from the FTW valid bits and the stored 80-bit FP data (assuming the stored data was not the contents of MMX registers) using the following table:
INSTRUCTION SET REFERENCE

FXSAVE—Save x87 FPU, MMX, SSE, and SSE2 State (Continued)

The J-bit is defined to be the 1-bit binary integer to the left of the decimal place in the significand. The M-bit is defined to be the most significant bit of the fractional portion of the significand (i.e., the bit immediately to the right of the decimal place).

When the M-bit is the most significant bit of the fractional portion of the significand, it must be 0 if the fraction is all 0’s.

Operation

DEST ← Save(x87 FPU, MMX, XMM7-XMM0, MXCSR);

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.

If memory operand is not aligned on a 16-byte boundary, regardless of segment. (See the description of the alignment check exception [#AC] below.)

#SS(0) For an illegal address in the SS segment.

#PF(fault-code) For a page fault.

#NM If TS in CR0 is set.

For all legal combinations above 0 Empty 11
FXSAVE—Save x87 FPU, MMX, SSE, and SSE2 State (Continued)

#UD If EM in CR0 is set.

If CPUID feature flag FXSR is 0.

If instruction is preceded by a LOCK override prefix.

#AC If this exception is disabled a general protection exception (#GP) is signaled if the memory operand is not aligned on a 16-byte boundary, as described above. If the alignment check exception (#AC) is enabled (and the CPL is 3), signaling of #AC is not guaranteed and may vary with implementation, as follows. In all implementations where #AC is not signaled, a general protection exception is signaled in its place. In addition, the width of the alignment check may also vary with implementation. For instance, for a given implementation, an alignment check exception might be signaled for a 2-byte misalignment, whereas a general protection exception might be signaled for all other misalignments (4-, 8-, or 16-byte misalignments).

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.

Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFFH.

#NM If TS in CR0 is set.

#UD If EM in CR0 is set.

If CPUID feature flag FXSR is 0.

If instruction is preceded by a LOCK override prefix.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC For unaligned memory reference if the current privilege level is 3.

Implementation Note

The order in which the processor signals general-protection (#GP) and page-fault (#PF) exceptions when they both occur on an instruction boundary is given in Table 5-2 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3. This order vary for the FXSAVE instruction for different IA-32 processor implementations.
FXTRACT—Extract Exponent and Significand

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D9 F4</td>
<td>FXTRACT</td>
<td>Separate value in ST(0) into exponent and significand, store exponent in ST(0), and push the significand onto the register stack.</td>
</tr>
</tbody>
</table>

**Description**

Separates the source value in the ST(0) register into its exponent and significand, stores the exponent in ST(0), and pushes the significand onto the register stack. Following this operation, the new top-of-stack register ST(0) contains the value of the original significand expressed as a floating-point value. The sign and significand of this value are the same as those found in the source operand, and the exponent is 3FFFH (biased value for a true exponent of zero). The ST(1) register contains the value of the original operand’s true (unbiased) exponent expressed as a floating-point value. (The operation performed by this instruction is a superset of the IEEE-recommended logb(x) function.)

This instruction and the F2XM1 instruction are useful for performing power and range scaling operations. The FXTRACT instruction is also useful for converting numbers in double extended-precision floating-point format to decimal representations (e.g., for printing or displaying).

If the floating-point zero-divide exception (#Z) is masked and the source operand is zero, an exponent value of $-\infty$ is stored in register ST(1) and 0 with the sign of the source operand is stored in register ST(0).

**Operation**

\[
\begin{align*}
\text{TEMP} & \leftarrow \text{Significand(ST(0))}; \\
\text{ST}(0) & \leftarrow \text{Exponent(ST(0))}; \\
\text{TOP} & \leftarrow \text{TOP} - 1; \\
\text{ST}(0) & \leftarrow \text{TEMP}; \\
\end{align*}
\]

**FPU Flags Affected**

- C1: Set to 0 if stack underflow occurred; set to 1 if stack overflow occurred.
- C0, C2, C3: Undefined.

**Floating-Point Exceptions**

- #IS: Stack underflow occurred.
- #IA: Source operand is an SNaN value or unsupported format.
FXTRACT—Extract Exponent and Significand (Continued)

#Z ST(0) operand is ±0.

#D Source operand is a denormal value.

**Protected Mode Exceptions**

#NM EM or TS in CR0 is set.

**Real-Address Mode Exceptions**

#NM EM or TS in CR0 is set.

**Virtual-8086 Mode Exceptions**

#NM EM or TS in CR0 is set.
FYL2X—Compute $y \times \log_2{x}$

<table>
<thead>
<tr>

**NOTES:**

- F Means finite floating-point value.
- * Indicates floating-point invalid-operation (#IA) exception.
- ** Indicates floating-point zero-divide (#Z) exception.

If the divide-by-zero exception is masked and register ST(0) contains ±0, the instruction returns $\infty$ with a sign that is the opposite of the sign of the source operand in register ST(0).

The FYL2X instruction is designed with a built-in multiplication to optimize the calculation of logarithms with an arbitrary positive base (b):

$$\log_b{x} \leftarrow (\log_2{b})^{-1} \times \log_2{x}$$

**Operation**

$$\text{ST}(1) \leftarrow \text{ST}(1) \times \log_2{\text{ST}(0)};$$

$$\text{PopRegisterStack;}$$
INSTRUCTION SET REFERENCE

FYL2X—Compute \( y \times \log_2 x \) (Continued)

FPU Flags Affected

- **C1**: Set to 0 if stack underflow occurred.
  - Indicates rounding direction if the inexact-result exception (#P) is generated: 0 ← not roundup; 1 ← roundup.
- **C0, C2, C3**: Undefined.

Floating-Point Exceptions

- **#IS**: Stack underflow occurred.
- **#IA**: Either operand is an SNaN or unsupported format.
  - Source operand in register ST(0) is a negative finite value (not −0).
- **#Z**: Source operand in register ST(0) is ±0.
- **#D**: Source operand is a denormal value.
- **#U**: Result is too small for destination format.
- **#O**: Result is too large for destination format.
- **#P**: Value cannot be represented exactly in destination format.

<td>FYL2XP1</td>
<td>Replace ST(1) with ( ST(1) \times \log_2(ST(0) + 1.0) ) and pop the register stack</td>
</tr>
</tbody>
</table>

**Description**

Computes the log epsilon \((ST(1) \times \log_2(ST(0) + 1.0))\), stores the result in register ST(1), and pops the FPU register stack. The source operand in ST(0) must be in the range:

\[-(1 - \sqrt{2}/2) \text{ to } (1 - \sqrt{2}/2)\]

The source operand in ST(1) can range from \(-\infty \) to \(+\infty \). If the ST(0) operand is outside of its acceptable range, the result is undefined and software should not rely on an exception being generated. Under some circumstances exceptions may be generated when ST(0) is out of range, but this behavior is implementation specific and not guaranteed.

The following table shows the results obtained when taking the log epsilon of various classes of numbers, assuming that underflow does not occur.

</tbody>
</table>

**NOTES:**

* F Means finite floating-point value.
* Indicates floating-point invalid-operation (#IA) exception.

This instruction provides optimal accuracy for values of epsilon [the value in register ST(0)] that are close to 0. For small epsilon (\( \varepsilon \)) values, more significant digits can be retained by using the FYL2XP1 instruction than by using \((\varepsilon+1)\) as an argument to the FYL2X instruction. The \((\varepsilon+1)\) expression is commonly found in compound interest and annuity calculations. The result can be simply converted into a value in another logarithm base by including a scale factor in the ST(1) source operand. The following equation is used to calculate the scale factor for a particular logarithm base, where \( n \) is the logarithm base desired for the result of the FYL2XP1 instruction:

\[
\text{scale factor } \leftarrow \log_n 2
\]
FYL2XP1—Compute $y \times \log_2(x + 1)$ (Continued)

Operation

$$\text{ST}(1) \leftarrow \text{ST}(1) \times \log_2(\text{ST}(0) + 1.0);$$
$$\text{PopRegisterStack};$$

FPU Flags Affected

$C1$ Set to 0 if stack underflow occurred.
Indicates rounding direction if the inexact-result exception (P) is generated: 0 $\leftarrow$ not roundup; 1 $\leftarrow$ roundup.

$C0, C2, C3$ Undefined.

Floating-Point Exceptions

#IS Stack underflow occurred.
#IA Either operand is an SNaN value or unsupported format.
#D Source operand is a denormal value.
#U Result is too small for destination format.

HLT—Halt

Description

Stops instruction execution and places the processor in a HALT state. An enabled interrupt (including NMI and SMI), a debug exception, the BINIT# signal, the INIT# signal, or the RESET# signal will resume execution. If an interrupt (including NMI) is used to resume execution after a HLT instruction, the saved instruction pointer (CS:EIP) points to the instruction following the HLT instruction.

The HLT instruction is a privileged instruction. When the processor is running in protected or virtual-8086 mode, the privilege level of a program or procedure must be 0 to execute the HLT instruction.

Operation

Enter Halt state;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.

Real-Address Mode Exceptions

None.

Virtual-8086 Mode Exceptions

#GP(0) If the current privilege level is not 0.
IDIV—Signed Divide

Description
Divides (signed) the value in the AX, DX:AX, or EDX:EAX registers (dividend) by the source operand (divisor) and stores the result in the AX (AH:AL), DX:AX, or EDX:EAX registers. The source operand can be a general-purpose register or a memory location. The action of this instruction depends on the operand size (dividend/divisor), as shown in the following table:

<table>
<thead>
<tr>
<th>Operand Size</th>
<th>Dividend</th>
<th>Divisor</th>
<th>Quotient</th>
<th>Remainder</th>
<th>Quotient Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word/byte</td>
<td>AX</td>
<td>r/m8</td>
<td>AL</td>
<td>AH</td>
<td>−128 to +127</td>
</tr>
<tr>
<td>Doubleword/word</td>
<td>DX:AX</td>
<td>r/m16</td>
<td>AX</td>
<td>DX</td>
<td>−32,768 to +32,767</td>
</tr>
<tr>
<td>Quadword/doubleword</td>
<td>EDX:EAX</td>
<td>r/m32</td>
<td>EAX</td>
<td>EDX</td>
<td>−2³² to 2³² – 1</td>
</tr>
</tbody>
</table>

Non-integral results are truncated (chopped) towards 0. The sign of the remainder is always the same as the sign of the dividend. The absolute value of the remainder is always less than the absolute value of the divisor. Overflow is indicated with the #DE (divide error) exception rather than with the OF (overflow) flag.

Operation
IF SRC ← 0
   THEN #DE; (* divide error *)
FI;
IF OperandSize ← 8 (* word/byte operation *)
   THEN
      temp ← AX / SRC; (* signed division *)
      IF (temp > 7FH) OR (temp < 80H)

</tbody>
</table>

**Description**

Performs a signed multiplication of two operands. This instruction has three forms, depending on the number of operands.

- **One-operand form.** This form is identical to that used by the MUL instruction. Here, the source operand (in a general-purpose register or memory location) is multiplied by the value in the AL, AX, or EAX register (depending on the operand size) and the product is stored in the AX, DX:AX, or EDX:EAX registers, respectively.

- **Two-operand form.** With this form the destination operand (the first operand) is multiplied by the source operand (second operand). The destination operand is a general-purpose register and the source operand is an immediate value, a general-purpose register, or a memory location. The product is then stored in the destination operand location.

- **Three-operand form.** This form requires a destination operand (the first operand) and two source operands (the second and the third operands). Here, the first source operand (which can be a general-purpose register or a memory location) is multiplied by the second source operand (an immediate value). The product is then stored in the destination operand (a general-purpose register).

When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.
INSTRUCTION SET REFERENCE

IMUL—Signed Multiply (Continued)

The CF and OF flags are set when significant bits are carried into the upper half of the result. The CF and OF flags are cleared when the result fits exactly in the lower half of the result.

The three forms of the IMUL instruction are similar in that the length of the product is calculated to twice the length of the operands. With the one-operand form, the product is stored exactly in the destination. With the two- and three-operand forms, however, result is truncated to the length of the destination before it is stored in the destination register. Because of this truncation, the CF or OF flag should be tested to ensure that no significant bits are lost.

The two- and three-operand forms may also be used with unsigned operands because the lower half of the product is the same regardless if the operands are signed or unsigned. The CF and OF flags, however, cannot be used to determine if the upper half of the result is non-zero.

Operation

IF (NumberOfOperands ← 1)
         THEN IF (OperandSize ← 8)
                THEN
                     AX ← AL * SRC (* signed multiplication *)
                     IF ((AH ← 00H) OR (AH ← FFH))
                         THEN CF ← 0; OF ← 0;
                         ELSE CF ← 1; OF ← 1;
                     FI;
                ELSE IF OperandSize ← 16
                        THEN
                             DX:AX ← AX * SRC (* signed multiplication *)
                             IF ((DX ← 0000H) OR (DX ← FFFFH))
                                 THEN CF ← 0; OF ← 0;
                                 ELSE CF ← 1; OF ← 1;
                             FI;
                         ELSE (* OperandSize ← 32 *)
                             EDX:EAX ← EAX * SRC (* signed multiplication *)
                             IF ((EDX ← 00000000H) OR (EDX ← FFFFFFFFH))
                                 THEN CF ← 0; OF ← 0;
                                 ELSE CF ← 1; OF ← 1;
                             FI;
                     FI;
                ELSE IF (NumberOfOperands ← 2)
                        THEN
                             temp ← DEST * SRC (* signed multiplication; temp is double DEST size*)
                             DEST ← DEST * SRC (* signed multiplication *)
                             IF temp ≠ DEST
                                 THEN CF ← 1; OF ← 1;
                                 ELSE CF ← 0; OF ← 0;
                             FI;
                         ELSE (* NumberOfOperands ← 3 *)

IMUL—Signed Multiply (Continued)

DEST ← SRC1 * SRC2 (* signed multiplication *)

temp ← SRC1 * SRC2 (* signed multiplication; temp is double SRC1 size *)

IF temp ≠ DEST
    THEN CF ← 1; OF ← 1;
    ELSE CF ← 0; OF ← 0;
FI;

Flags Affected

For the one operand form of the instruction, the CF and OF flags are set when significant bits are carried into the upper half of the result and cleared when the result fits exactly in the lower half of the result. For the two- and three-operand forms of the instruction, the CF and OF flags are set when the result must be truncated to fit in the destination operand size and cleared when the result fits exactly in the destination operand size. The SF, ZF, AF, and PF flags are undefined.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
IN—Input from Port

Description
Copies the value from the I/O port specified with the second operand (source operand) to the destination operand (first operand). The source operand can be a byte-immediate or the DX register; the destination operand can be register AL, AX, or EAX, depending on the size of the port being accessed (8, 16, or 32 bits, respectively). Using the DX register as a source operand allows I/O port addresses from 0 to 65,535 to be accessed; using a byte immediate allows I/O port addresses 0 to 255 to be accessed.

When accessing an 8-bit I/O port, the opcode determines the port size; when accessing a 16- and 32-bit I/O port, the operand-size attribute determines the port size.

At the machine code level, I/O instructions are shorter when accessing 8-bit I/O ports. Here, the upper eight bits of the port address will be 0.

This instruction is only useful for accessing I/O ports located in the processor’s I/O address space. See Chapter 12, Input/Output, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for more information on accessing I/O ports in the I/O address space.

Operation
IF ((PE ← 1) AND ((CPL > IOPL) OR (VM ← 1)))
    THEN (* Protected mode with CPL > IOPL or virtual-8086 mode *)
        IF (Any I/O Permission Bit for I/O port being accessed ← 1)
            THEN (* I/O operation is not allowed *)
                #GP(0);
        ELSE (* I/O operation is allowed *)
            DEST ← SRC; (* Reads from selected I/O port *)
    FI;
ELSE (Real Mode or Protected Mode with CPL ≤ IOPL *)
    DEST ← SRC; (* Reads from selected I/O port *)
FI;

Flags Affected
None.
IN—Input from Port (Continued)

Protected Mode Exceptions

#GP(0) If the CPL is greater than (has less privilege) the I/O privilege level (IOPL) and any of the corresponding I/O permission bits in TSS for the I/O port being accessed is 1.

Real-Address Mode Exceptions

None.

Virtual-8086 Mode Exceptions

#GP(0) If any of the I/O permission bits in the TSS for the I/O port being accessed is 1.
INSTRUCTION SET REFERENCE

INC—Increment by 1

<td>INC r16</td>
<td>Increment word register by 1</td>
</tr>
<tr>
<td>40+rd</td>
<td>INC r32</td>
<td>Increment doubleword register by 1</td>
</tr>
</tbody>
</table>

Description
Adds 1 to the destination operand, while preserving the state of the CF flag. The destination operand can be a register or a memory location. This instruction allows a loop counter to be updated without disturbing the CF flag. (Use a ADD instruction with an immediate operand of 1 to perform an increment operation that does updates the CF flag.)

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation
DEST ← DEST +1;

Flags Affected
The CF flag is not affected. The OF, SF, ZF, AF, and PF flags are set according to the result.

Protected Mode Exceptions

#GP(0) If the destination operand is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
INC—Increment by 1 (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
INS/INSB/INSW/INSD—Input from Port to String

Description

Copies the data from the I/O port specified with the source operand (second operand) to the destination operand (first operand). The source operand is an I/O port address (from 0 to 65,535) that is read from the DX register. The destination operand is a memory location, the address of which is read from either the ES:EDI or the ES:DI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). (The ES segment cannot be overridden with a segment override prefix.) The size of the I/O port being accessed (that is, the size of the source and destination operands) is determined by the opcode for an 8-bit I/O port or by the operand-size attribute of the instruction for a 16- or 32-bit I/O port.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the INS mnemonic) allows the source and destination operands to be specified explicitly. Here, the source operand must be “DX,” and the destination operand should be a symbol that indicates the size of the I/O port and the destination address. This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the destination operand symbol must specify the correct type (size) of the operand (byte, word, or doubleword), but it does not have to specify the correct location. The location is always specified by the ES:(E)DI registers, which must be loaded correctly before the INS instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the INS instructions. Here also DX is assumed by the processor to be the source operand and ES:(E)DI is assumed to be the destination operand. The size of the I/O port is specified with the choice of mnemonic: INSB (byte), INSW (word), or INSD (doubleword).

After the byte, word, or doubleword is transfer from the I/O port to the memory location, the (E)DI register is incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)DI register is incremented; if the DF flag is 1, the (E)DI register is decremented.) The (E)DI register is incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.
INS/INSB/INSW/INSD—Input from Port to String (Continued)

The INS, INSB, INSW, and INSD instructions can be preceded by the REP prefix for block input of ECX bytes, words, or doublewords. See “REP/REPE/REPZ/REPNE /REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.

These instructions are only useful for accessing I/O ports located in the processor’s I/O address space. See Chapter 12, Input/Output, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for more information on accessing I/O ports in the I/O address space.

Flags Affected

None.
INS/INSB/INSW/INSD—Input from Port to String (Continued)

Protected Mode Exceptions

#GP(0)  If the CPL is greater than (has less privilege) the I/O privilege level (IOPL) and any of the corresponding I/O permission bits in TSS for the I/O port being accessed is 1.
   If the destination is located in a nonwritable segment.
   If an illegal memory operand effective address in the ES segments is given.

#PF(fault-code)  If a page fault occurs.

#AC(0)  If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS  If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0)  If any of the I/O permission bits in the TSS for the I/O port being accessed is 1.

#PF(fault-code)  If a page fault occurs.

#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
INT n/INTO/INT 3—Call to Interrupt Procedure

Description

The INT n instruction generates a call to the interrupt or exception handler specified with the destination operand (see the section titled “Interrupts and Exceptions” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). The destination operand specifies an interrupt vector number from 0 to 255, encoded as an 8-bit unsigned intermediate value. Each interrupt vector number provides an index to a gate descriptor in the IDT. The first 32 interrupt vector numbers are reserved by Intel for system use. Some of these interrupts are used for internally generated exceptions.

The INTO instruction is a special mnemonic for calling overflow exception (#OF), interrupt vector number 4. The overflow interrupt checks the OF flag in the EFLAGS register and calls the overflow interrupt handler if the OF flag is set to 1.

The INT 3 instruction generates a special one byte opcode (CC) that is intended for calling the debug exception handler. (This one byte form is valuable because it can be used to replace the first byte of any instruction with a breakpoint, including other one byte instructions, without over-writing other code). To further support its function as a debug breakpoint, the interrupt generated with the CC opcode also differs from the regular software interrupts as follows:

- Interrupt redirection does not happen when in VME mode; the interrupt is handled by a protected-mode handler.
- The virtual-8086 mode IOPL checks do not occur. The interrupt is taken without faulting at any IOPL level.

Note that the “normal” 2-byte opcode for INT 3 (CD03) does not have these special features. Intel and Microsoft assemblers will not generate the CD03 opcode from any mnemonic, but this opcode can be created by direct numeric code definition or by self-modifying code.

The action of the INT n instruction (including the INTO and INT 3 instructions) is similar to that of a far call made with the CALL instruction. The primary difference is that with the INT n instruction, the EFLAGS register is pushed onto the stack before the return address. (The return address is a far address consisting of the current values of the CS and EIP registers.) Returns from interrupt procedures are handled with the IRET instruction, which pops the EFLAGS information and return address from the stack.
INT n/INTO/INT 3—Call to Interrupt Procedure (Continued)

The interrupt vector number specifies an interrupt descriptor in the interrupt descriptor table (IDT); that is, it provides index into the IDT. The selected interrupt descriptor in turn contains a pointer to an interrupt or exception handler procedure. In protected mode, the IDT contains an array of 8-byte descriptors, each of which is an interrupt gate, trap gate, or task gate. In real-address mode, the IDT is an array of 4-byte far pointers (2-byte code segment selector and a 2-byte instruction pointer), each of which point directly to a procedure in the selected segment. (Note that in real-address mode, the IDT is called the interrupt vector table, and its pointers are called interrupt vectors.)

The following decision table indicates which action in the lower portion of the table is taken given the conditions in the upper portion of the table. Each Y in the lower section of the decision table represents a procedure defined in the “Operation” section for this instruction (except #GP).

NOTES:
– Don't Care.
Y Yes, Action Taken.
Blank Action Not Taken.
INT n/INTO/INT 3—Call to Interrupt Procedure (Continued)

When the processor is executing in virtual-8086 mode, the IOPL determines the action of the INT n instruction. If the IOPL is less than 3, the processor generates a general protection exception (#GP); if the IOPL is 3, the processor executes a protected mode interrupt to privilege level 0. The interrupt gate’s DPL must be set to three and the target CPL of the interrupt handler procedure must be 0 to execute the protected mode interrupt to privilege level 0.

The interrupt descriptor table register (IDTR) specifies the base linear address and limit of the IDT. The initial base address value of the IDTR after the processor is powered up or reset is 0.

Operation

The following operational description applies not only to the INT n and INTO instructions, but also to external interrupts and exceptions.

IF PE=0
    THEN
        GOTO REAL-ADDRESS-MODE;
    ELSE (* PE=1 *)
        IF (VM=1 AND IOPL < 3 AND INT n)
            THEN
                #GP(0);
            ELSE (* protected mode or virtual-8086 mode interrupt *)
                GOTO PROTECTED-MODE;
        FI;
    FI;

REAL-ADDRESS-MODE:
    IF ((DEST ∗ 4) + 3) is not within IDT limit THEN #GP; FI;
    IF stack not large enough for a 6-byte return information THEN #SS; FI;
    Push (EFLAGS[15:0]);
    IF ← 0; (* Clear interrupt flag *)
    TF ← 0; (* Clear trap flag *)
    AC ← 0; (* Clear AC flag *)
    Push(CS);
    Push(IP);
    (* No error codes are pushed *)
    CS ← IDT(Descriptor (vector_number ∗ 4), selector));
    EIP ← IDT(Descriptor (vector_number ∗ 4), offset)); (* 16 bit offset AND 0000FFFFH *)
END;

PROTECTED-MODE:
    IF ((DEST ∗ 8) + 7) is not within IDT limits
        OR selected IDT descriptor is not an interrupt-, trap-, or task-gate type
            THEN #GP((DEST ∗ 8) + 2 + EXT);

Flags Affected

The EFLAGS register is pushed onto the stack. The IF, TF, NT, AC, RF, and VM flags may be cleared, depending on the mode of operation of the processor when the INT instruction is executed (see the “Operation” section). If the interrupt uses a task gate, any flags may be set or cleared, controlled by the EFLAGS image in the new task’s TSS.

Protected Mode Exceptions

#GP(0) If the instruction pointer in the IDT or in the interrupt-, trap-, or task gate is beyond the code segment limits.
INT n/INTO/INT 3—Call to Interrupt Procedure (Continued)

#GP(selector)  
If the segment selector in the interrupt-, trap-, or task gate is null.
If a interrupt-, trap-, or task gate, code segment, or TSS segment selector index is outside its descriptor table limits.
If the interrupt vector number is outside the IDT limits.
If an IDT descriptor is not an interrupt-, trap-, or task-descriptor.
If an interrupt is generated by the INT n, INT 3, or INTO instruction and the DPL of an interrupt-, trap-, or task-descriptor is less than the CPL.
If the segment selector in an interrupt- or trap-gate does not point to a segment descriptor for a code segment.
If the segment selector for a TSS has its local/global bit set for local.
If a TSS segment descriptor specifies that the TSS is busy or not available.

#SS(0)  
If pushing the return address, flags, or error code onto the stack exceeds the bounds of the stack segment and no stack switch occurs.

#SS(selector)  
If the SS register is being loaded and the segment pointed to is marked not present.
If pushing the return address, flags, error code, or stack segment pointer exceeds the bounds of the new stack segment when a stack switch occurs.

#NP(selector)  
If code segment, interrupt-, trap-, or task gate, or TSS is not present.

#TS(selector)  
If the RPL of the stack segment selector in the TSS is not equal to the DPL of the code segment being accessed by the interrupt or trap gate.
If DPL of the stack segment descriptor pointed to by the stack segment selector in the TSS is not equal to the DPL of the code segment descriptor for the interrupt or trap gate.
If the stack segment selector in the TSS is null.
If the stack segment for the TSS is not a writable data segment.
If segment-selector index for stack segment is outside descriptor table limits.

#PF(fault-code)  
If a page fault occurs.

Real-Address Mode Exceptions

#GP  
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the interrupt vector number is outside the IDT limits.
INT n/INTO/INT 3—Call to Interrupt Procedure (Continued)

#SS If stack limit violation on push.
If pushing the return address, flags, or error code onto the stack exceeds the bounds of the stack segment.

Virtual-8086 Mode Exceptions

#GP(0) (For INT n, INTO, or BOUND instruction) If the IOPL is less than 3 or the DPL of the interrupt-, trap-, or task-gate descriptor is not equal to 3.
If the instruction pointer in the IDT or in the interrupt-, trap-, or task gate is beyond the code segment limits.

#GP(selector) If the segment selector in the interrupt-, trap-, or task gate is null.
If a interrupt-, trap-, or task gate, code segment, or TSS segment selector index is outside its descriptor table limits.
If the interrupt vector number is outside the IDT limits.
If an IDT descriptor is not an interrupt-, trap-, or task-descriptor.
If an interrupt is generated by the INT n instruction and the DPL of an interrupt-, trap-, or task descriptor is less than the CPL.
If the segment selector in an interrupt- or trap-gate does not point to a segment descriptor for a code segment.
If the segment selector for a TSS has its local/global bit set for local.

#SS(selector) If the SS register is being loaded and the segment pointed to is marked not present.
If pushing the return address, flags, error code, stack segment pointer, or data segments exceeds the bounds of the stack segment.

#NP(selector) If code segment, interrupt-, trap-, or task gate, or TSS is not present.

#TS(selector) If the RPL of the stack segment selector in the TSS is not equal to the DPL of the code segment being accessed by the interrupt or trap gate.
If DPL of the stack segment descriptor for the TSS's stack segment is not equal to the DPL of the code segment descriptor for the interrupt or trap gate.
If the stack segment selector in the TSS is null.
If the stack segment for the TSS is not a writable data segment.
If segment-selector index for stack segment is outside descriptor table limits.
INT n/INTO/INT 3—Call to Interrupt Procedure (Continued)

#PF(fault-code) If a page fault occurs.
#BP If the INT 3 instruction is executed.
#OF If the INTO instruction is executed and the OF flag is set.

**Description**

Invalidate (flushes) the processor’s internal caches and issues a special-function bus cycle that directs external caches to also flush themselves. Data held in internal caches is not written back to main memory.

After executing this instruction, the processor does not wait for the external caches to complete their flushing operation before proceeding with instruction execution. It is the responsibility of hardware to respond to the cache flush signal.

The INVD instruction is a privileged instruction. When the processor is running in protected mode, the CPL of a program or procedure must be 0 to execute this instruction.

Use this instruction with care. Data cached internally and not written back to main memory will be lost. Unless there is a specific requirement or benefit to flushing caches without writing back modified cache lines (for example, testing or fault recovery where cache coherency with main memory is not a concern), software should use the WBINVD instruction.

**IA-32 Architecture Compatibility**

The INVD instruction is implementation dependent, and its function may be implemented differently on future IA-32 processors. This instruction is not supported on IA-32 processors earlier than the Intel486 processor.

**Operation**

Flush(InternalCaches);
SignalFlush(ExternalCaches);
Continue (* Continue execution);

**Flags Affected**

None.

**Protected Mode Exceptions**

#GP(0) If the current privilege level is not 0.

**Real-Address Mode Exceptions**

None.
INVD—Invalidate Internal Caches (Continued)

Virtual-8086 Mode Exceptions

#GP(0) The INVD instruction cannot be executed in virtual-8086 mode.
INVLPGL—Invalid TLB Entry

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 01/7</td>
<td>INVLPG m</td>
<td>Invalidate TLB Entry for page that contains m</td>
</tr>
</tbody>
</table>

**Description**

Invalidates (flushes) the translation lookaside buffer (TLB) entry specified with the source operand. The source operand is a memory address. The processor determines the page that contains that address and flushes the TLB entry for that page.

The INVLPG instruction is a privileged instruction. When the processor is running in protected mode, the CPL of a program or procedure must be 0 to execute this instruction.

The INVLPG instruction normally flushes the TLB entry only for the specified page; however, in some cases, it flushes the entire TLB. See “MOV—Move to/from Control Registers” in this chapter for further information on operations that flush the TLB.

**IA-32 Architecture Compatibility**

The INVLPG instruction is implementation dependent, and its function may be implemented differently on future IA-32 processors. This instruction is not supported on IA-32 processors earlier than the Intel486 processor.

**Operation**

Flush(RelevantTLBEntries);
Continue (* Continue execution);

**Flags Affected**

None.

**Protected Mode Exceptions**

- #GP(0) If the current privilege level is not 0.
- #UD Operand is a register.

**Real-Address Mode Exceptions**

- #UD Operand is a register.

**Virtual-8086 Mode Exceptions**

- #GP(0) The INVLPG instruction cannot be executed at the virtual-8086 mode.
IRET/IRETD—Interrupt Return

Description
Returns program control from an exception or interrupt handler to a program or procedure that was interrupted by an exception, an external interrupt, or a software-generated interrupt. These instructions are also used to perform a return from a nested task. (A nested task is created when a CALL instruction is used to initiate a task switch or when an interrupt or exception causes a task switch to an interrupt or exception handler.) See the section titled “Task Linking” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3.

IRET and IRETD are mnemonics for the same opcode. The IRETD mnemonic (interrupt return double) is intended for use when returning from an interrupt when using the 32-bit operand size; however, most assemblers use the IRET mnemonic interchangeably for both operand sizes.

In Real-Address Mode, the IRET instruction performs a far return to the interrupted program or procedure. During this operation, the processor pops the return instruction pointer, return code segment selector, and EFLAGS image from the stack to the EIP, CS, and EFLAGS registers, respectively, and then resumes execution of the interrupted program or procedure.

In Protected Mode, the action of the IRET instruction depends on the settings of the NT (nested task) and VM flags in the EFLAGS register and the VM flag in the EFLAGS image stored on the current stack. Depending on the setting of these flags, the processor performs the following types of interrupt returns:

- Return from virtual-8086 mode.
- Return to virtual-8086 mode.
- Intra-privilege level return.
- Inter-privilege level return.
- Return from nested task (task switch).

If the NT flag (EFLAGS register) is cleared, the IRET instruction performs a far return from the interrupt procedure, without a task switch. The code segment being returned to must be equally or less privileged than the interrupt handler routine (as indicated by the RPL field of the code segment selector popped from the stack). As with a real-address mode interrupt return, the IRET instruction pops the return instruction pointer, return code segment selector, and EFLAGS image from the stack to the EIP, CS, and EFLAGS registers, respectively, and then resumes execution of the interrupted program or procedure. If the return is to another privilege level, the IRET instruction also pops the stack pointer and SS from the stack, before resuming program execution. If the return is to virtual-8086 mode, the processor also pops the data segment registers from the stack.

<table>

<td>Interrupt return (32-bit operand size)</td>
</tr>
</tbody>
</table>
IRET/IRETD—Interrupt Return (Continued)

If the NT flag is set, the IRET instruction performs a task switch (return) from a nested task (a task called with a CALL instruction, an interrupt, or an exception) back to the calling or interrupted task. The updated state of the task executing the IRET instruction is saved in its TSS. If the task is re-entered later, the code that follows the IRET instruction is executed.

Operation

IF PE ← 0

END:

Flags Affected

All the flags and fields in the EFLAGS register are potentially modified, depending on the mode of operation of the processor. If performing a return from a nested task to a previous task, the EFLAGS register will be modified according to the EFLAGS image stored in the previous task’s TSS.
IRET/IRETD—Interrupt Return (Continued)

Protected Mode Exceptions

#GP(0) If the return code or stack segment selector is null.
    If the return instruction pointer is not within the return code segment limit.
#GP(selector) If a segment selector index is outside its descriptor table limits.
    If the return code segment selector RPL is greater than the CPL.
    If the DPL of a conforming-code segment is greater than the return code
    segment selector RPL.
    If the DPL for a nonconforming-code segment is not equal to the RPL of
    the code segment selector.
    If the stack segment descriptor DPL is not equal to the RPL of the return
    code segment selector.
    If the stack segment is not a writable data segment.
    If the stack segment selector RPL is not equal to the RPL of the return code
    segment selector.
    If the segment descriptor for a code segment does not indicate it is a code
    segment.
    If the segment selector for a TSS has its local/global bit set for local.
#SS(0) If the top bytes of stack are not within stack limits.
#NP(selector) If the return code or stack segment is not present.
#PF(fault-code) If a page fault occurs.
#AC(0) If an unaligned memory reference occurs when the CPL is 3 and alignment
    checking is enabled.

Real-Address Mode Exceptions

#GP If the return instruction pointer is not within the return code segment limit.
#SS If the top bytes of stack are not within stack limits.

Virtual-8086 Mode Exceptions

#GP(0) If the return instruction pointer is not within the return code segment limit.
    IF IOPL not equal to 3
#PF(fault-code) If a page fault occurs.
IRET/IRETD—Interrupt Return (Continued)

#SS(0)    If the top bytes of stack are not within stack limits.

#AC(0)    If an unaligned memory reference occurs and alignment checking is enabled.

Description

Checks the state of one or more of the status flags in the EFLAGS register (CF, OF, PF, SF, and ZF) and, if the flags are in the specified state (condition), performs a jump to the target instruction specified by the destination operand. A condition code (cc) is associated with each instruction to indicate the condition being tested for. If the condition is not satisfied, the jump is not performed and execution continues with the instruction following the Jcc instruction.

The target instruction is specified with a relative offset (a signed offset relative to the current value of the instruction pointer in the EIP register). A relative offset (rel8, rel16, or rel32) is generally specified as a label in assembly code, but at the machine code level, it is encoded as a signed, 8-bit or 32-bit immediate value, which is added to the instruction pointer. Instruction coding is most efficient for offsets of –128 to +127. If the operand-size attribute is 16, the upper two bytes of the EIP register are cleared to 0s, resulting in a maximum instruction pointer size of 16 bits.
Jcc—Jump if Condition Is Met (Continued)

The conditions for each Jcc mnemonic are given in the “Description” column of the table on the preceding page. The terms “less” and “greater” are used for comparisons of signed integers and the terms “above” and “below” are used for unsigned integers.

Because a particular state of the status flags can sometimes be interpreted in two ways, two mnemonics are defined for some opcodes. For example, the JA (jump if above) instruction and the JNBE (jump if not below or equal) instruction are alternate mnemonics for the opcode 77H.

The Jcc instruction does not support far jumps (jumps to other code segments). When the target for the conditional jump is in a different segment, use the opposite condition from the condition being tested for the Jcc instruction, and then access the target with an unconditional far jump (JMP instruction) to the other segment. For example, the following conditional far jump is illegal:

JZ FARLABEL;

To accomplish this far jump, use the following two instructions:

JNZ BEYOND;
JMP FARLABEL;
BEYOND:

The JECXZ and JCXZ instructions differs from the other Jcc instructions because they do not check the status flags. Instead they check the contents of the ECX and CX registers, respectively, for 0. Either the CX or ECX register is chosen according to the address-size attribute. These instructions are useful at the beginning of a conditional loop that terminates with a conditional loop instruction (such as LOOPNE). They prevent entering the loop when the ECX or CX register is equal to 0, which would cause the loop to execute $2^{32}$ or 64K times, respectively, instead of zero times.

All conditional jumps are converted to code fetches of one or two cache lines, regardless of jump address or cacheability.

Operation

IF condition
THEN
  EIP ← EIP + SignExtend(DEST);
  IF OperandSize ← 16
    THEN
      EIP ← EIP AND 0000FFFFH;
    FI;
  ELSE (* OperandSize = 32 *)
    IF EIP < CS.Base OR EIP > CS.Limit
      #GP
    FI;
  FI;
Jcc—Jump if Condition Is Met (Continued)

Flags Affected
None.

Protected Mode Exceptions
#GP(0) If the offset being jumped to is beyond the limits of the CS segment.

Real-Address Mode Exceptions
#GP If the offset being jumped to is beyond the limits of the CS segment or is outside of the effective address space from 0 to FFFFH. This condition can occur if a 32-bit address size override prefix is used.

Virtual-8086 Mode Exceptions
Same exceptions as in Real Address Mode

Description

Transfers program control to a different point in the instruction stream without recording return information. The destination (target) operand specifies the address of the instruction being jumped to. This operand can be an immediate value, a general-purpose register, or a memory location.

This instruction can be used to execute four different types of jumps:

- Near jump—A jump to an instruction within the current code segment (the segment currently pointed to by the CS register), sometimes referred to as an intrasegment jump.
- Short jump—A near jump where the jump range is limited to –128 to +127 from the current EIP value.
- Far jump—A jump to an instruction located in a different segment than the current code segment but at the same privilege level, sometimes referred to as an intersegment jump.
- Task switch—A jump to an instruction located in a different task.

A task switch can only be executed in protected mode (see Chapter 6, Task Management, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for information on performing task switches with the JMP instruction).

Near and Short Jumps. When executing a near jump, the processor jumps to the address (within the current code segment) that is specified with the target operand. The target operand specifies either an absolute offset (that is an offset from the base of the code segment) or a relative offset (a signed displacement relative to the current value of the instruction pointer in the EIP register). A near jump to a relative offset of 8-bits (rel8) is referred to as a short jump. The CS register is not changed on near and short jumps.

An absolute offset is specified indirectly in a general-purpose register or a memory location (r/m16 or r/m32). The operand-size attribute determines the size of the target operand (16 or 32 bits). Absolute offsets are loaded directly into the EIP register. If the operand-size attribute is 16, the upper two bytes of the EIP register are cleared to 0s, resulting in a maximum instruction pointer size of 16 bits.
JMP—Jump (Continued)

A relative offset (rel8, rel16, or rel32) is generally specified as a label in assembly code, but at the machine code level, it is encoded as a signed 8-, 16-, or 32-bit immediate value. This value is added to the value in the EIP register. (Here, the EIP register contains the address of the instruction following the JMP instruction). When using relative offsets, the opcode (for short vs. near jumps) and the operand-size attribute (for near relative jumps) determines the size of the target operand (8, 16, or 32 bits).

Far Jumps in Real-Address or Virtual-8086 Mode. When executing a far jump in real-address or virtual-8086 mode, the processor jumps to the code segment and offset specified with the target operand. Here the target operand specifies an absolute far address either directly with a pointer (ptr16:16 or ptr16:32) or indirectly with a memory location (m16:16 or m16:32). With the pointer method, the segment and address of the called procedure is encoded in the instruction, using a 4-byte (16-bit operand size) or 6-byte (32-bit operand size) far address immediate. With the indirect method, the target operand specifies a memory location that contains a 4-byte (16-bit operand size) or 6-byte (32-bit operand size) far address. The far address is loaded directly into the CS and EIP registers. If the operand-size attribute is 16, the upper two bytes of the EIP register are cleared to 0s.

Far Jumps in Protected Mode. When the processor is operating in protected mode, the JMP instruction can be used to perform the following three types of far jumps:

- A far jump to a conforming or non-conforming code segment.
- A far jump through a call gate.
- A task switch.

(The JMP instruction cannot be used to perform inter-privilege-level far jumps.)

In protected mode, the processor always uses the segment selector part of the far address to access the corresponding descriptor in the GDT or LDT. The descriptor type (code segment, call gate, task gate, or TSS) and access rights determine the type of jump to be performed.

If the selected descriptor is for a code segment, a far jump to a code segment at the same privilege level is performed. (If the selected code segment is at a different privilege level and the code segment is non-conforming, a general-protection exception is generated.) A far jump to the same privilege level in protected mode is very similar to one carried out in real-address or virtual-8086 mode. The target operand specifies an absolute far address either directly with a pointer (ptr16:16 or ptr16:32) or indirectly with a memory location (m16:16 or m16:32). The operand-size attribute determines the size of the offset (16 or 32 bits) in the far address. The new code segment selector and its descriptor are loaded into CS register, and the offset from the instruction is loaded into the EIP register. Note that a call gate (described in the next paragraph) can also be used to perform far call to a code segment at the same privilege level. Using this mechanism provides an extra level of indirection and is the preferred method of making jumps between 16-bit and 32-bit code segments.
JMP—Jump (Continued)

When executing a far jump through a call gate, the segment selector specified by the target operand identifies the call gate. (The offset part of the target operand is ignored.) The processor then jumps to the code segment specified in the call gate descriptor and begins executing the instruction at the offset specified in the call gate. No stack switch occurs. Here again, the target operand can specify the far address of the call gate either directly with a pointer (ptr16:16 or ptr16:32) or indirectly with a memory location (m16:16 or m16:32).

Executing a task switch with the JMP instruction, is somewhat similar to executing a jump through a call gate. Here the target operand specifies the segment selector of the task gate for the task being switched to (and the offset part of the target operand is ignored). The task gate in turn points to the TSS for the task, which contains the segment selectors for the task’s code and stack segments. The TSS also contains the EIP value for the next instruction that was to be executed before the task was suspended. This instruction pointer value is loaded into EIP register so that the task begins executing again at this next instruction.

The JMP instruction can also specify the segment selector of the TSS directly, which eliminates the indirection of the task gate. See Chapter 6, Task Management, in IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for detailed information on the mechanics of a task switch.

Note that when you execute a task switch with a JMP instruction, the nested task flag (NT) is not set in the EFLAGS register and the new TSS’s previous task link field is not loaded with the old task’s TSS selector. A return to the previous task can thus not be carried out by executing the IRET instruction. Switching tasks with the JMP instruction differs in this regard from the CALL instruction which does set the NT flag and save the previous task link information, allowing a return to the calling task with an IRET instruction.

Flags Affected
All flags are affected if a task switch occurs; no flags are affected if a task switch does not occur.

Protected Mode Exceptions

#GP(0) If offset in target operand, call gate, or TSS is beyond the code segment limits.
If the segment selector in the destination operand, call gate, task gate, or TSS is null.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#GP(selector) If segment selector index is outside descriptor table limits.
If the segment descriptor pointed to by the segment selector in the destination operand is not for a conforming-code segment, nonconforming-code segment, call gate, task gate, or task state segment.
If the DPL for a nonconforming-code segment is not equal to the CPL
(When not using a call gate.) If the RPL for the segment’s segment selector is greater than the CPL.
If the DPL for a conforming-code segment is greater than the CPL.
INSTRUCTION SET REFERENCE

JMP—Jump (Continued)

If the DPL from a call-gate, task-gate, or TSS segment descriptor is less than the CPL or than the RPL of the call-gate, task-gate, or TSS’s segment selector.

If the segment descriptor for selector in a call gate does not indicate it is a code segment.

If the segment descriptor for the segment selector in a task gate does not indicate available TSS.

If the segment selector for a TSS has its local/global bit set for local.

If a TSS segment descriptor specifies that the TSS is busy or not available.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NP (selector) If the code segment being accessed is not present.

If call gate, task gate, or TSS not present.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. (Only occurs when fetching target from memory.)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If the target operand is beyond the code segment limits.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made. (Only occurs when fetching target from memory.)
LAHF—Load Status Flags into AH Register

<table>
<thead>

</tr>
<tr>
<td>0F 02 /r</td>
<td>LAR r32,r/m32</td>
<td>r32 ← r/m32 masked by 00FxFF00H</td>
</tr>
</tbody>
</table>

Description

Loads the access rights from the segment descriptor specified by the second operand (source operand) into the first operand (destination operand) and sets the ZF flag in the EFLAGS register. The source operand (which can be a register or a memory location) contains the segment selector for the segment descriptor being accessed. The destination operand is a general-purpose register.

The processor performs access checks as part of the loading process. Once loaded in the destination register, software can perform additional checks on the access rights information.

When the operand size is 32 bits, the access rights for a segment descriptor include the type and DPL fields and the S, P, AVL, D/B, and G flags, all of which are located in the second doubleword (bytes 4 through 7) of the segment descriptor. The doubleword is masked by 00FXFF00H before it is loaded into the destination operand. When the operand size is 16 bits, the access rights include the type and DPL fields. Here, the two lower-order bytes of the doubleword are masked by FF00H before being loaded into the destination operand.

This instruction performs the following checks before it loads the access rights in the destination register:

- Checks that the segment selector is not null.
- Checks that the segment selector points to a descriptor that is within the limits of the GDT or LDT being accessed
- Checks that the descriptor type is valid for this instruction. All code and data segment descriptors are valid for (can be accessed with) the LAR instruction. The valid system segment and gate descriptor types are given in the following table.
- If the segment is not a conforming code segment, it checks that the specified segment descriptor is visible at the CPL (that is, if the CPL and the RPL of the segment selector are less than or equal to the DPL of the segment selector).

If the segment descriptor cannot be accessed or is an invalid type for the instruction, the ZF flag is cleared and no access rights are loaded in the destination operand.

The LAR instruction can only be executed in protected mode.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. (Only occurs when fetching target from memory.)

Real-Address Mode Exceptions

#UD The LAR instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD The LAR instruction cannot be executed in virtual-8086 mode.
LDMXCSR—Load MXCSR Register

Description
Loads the source operand into the MXCSR control/status register. The source operand is a 32-bit memory location. See “MXCSR Control and Status Register” in Chapter 10, of the IA-32 Intel Architecture Software Developer’s Manual, Volume I, for a description of the MXCSR register and its contents.

The LDMXCSR instruction is typically used in conjunction with the STMXCSR instruction, which stores the contents of the MXCSR register in memory.

The default MXCSR value at reset is 1F80H.

If a LDMXCSR instruction clears a SIMD floating-point exception mask bit and sets the corresponding exception flag bit, a SIMD floating-point exception will not be immediately generated. The exception will be generated only upon the execution of the next SSE or SSE2 instruction that causes that particular SIMD floating-point exception to be reported.

Operation
MXCSR ← m32;

C/C++ Compiler Intrinsic Equivalent
_mm_setcsr(unsigned int i)

Numeric Exceptions
None.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS, or GS segments.

#SS(0) For an illegal address in the SS segment.

#PF(fault-code) For a page fault.

#NM If TS in CR0 is set.
LDMXCSR—Load MXCSR Register (Continued)

#UD If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real Address Mode Exceptions

Interrupt 13 If any part of the operand would lie outside of the effective address space from 0 to FFFFH.
#NM If TS in CR0 is set.
#UD If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

Virtual 8086 Mode Exceptions

Same exceptions as in Real Address Mode.
#PF(fault-code) For a page fault.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

</table>

Description

Loads a far pointer (segment selector and offset) from the second operand (source operand) into a segment register and the first operand (destination operand). The source operand specifies a 48-bit or a 32-bit pointer in memory depending on the current setting of the operand-size attribute (32 bits or 16 bits, respectively). The instruction opcode and the destination operand specify a segment register/general-purpose register pair. The 16-bit segment selector from the source operand is loaded into the segment register specified with the opcode (DS, SS, ES, FS, or GS). The 32-bit or 16-bit offset is loaded into the register specified with the destination operand.

If one of these instructions is executed in protected mode, additional information from the segment descriptor pointed to by the segment selector in the source operand is loaded in the hidden part of the selected segment register.

Also in protected mode, a null selector (values 0000 through 0003) can be loaded into DS, ES, FS, or GS registers without causing a protection exception. (Any subsequent reference to a segment whose corresponding segment register is loaded with a null selector, causes a general-protection exception (#GP) and no memory reference to the segment occurs.)

Operation

IF ProtectedMode
    THEN IF SS is loaded
        THEN IF SegmentSelector ← null
            THEN #GP(0);
        FI;
    ELSE IF Segment selector index is not within descriptor table limits
        OR Segment selector RPL ≠ CPL
        OR Access rights indicate nonwritable data segment
        OR DPL ≠ CPL

<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8D /r</td>
<td>LEA r16,m</td>
<td>Store effective address for m in register r16</td>
</tr>
<tr>
<td>8D /r</td>
<td>LEA r32,m</td>
<td>Store effective address for m in register r32</td>
</tr>
</tbody>
</table>

**Description**

Computes the effective address of the second operand (the source operand) and stores it in the first operand (destination operand). The source operand is a memory address (offset part) specified with one of the processors addressing modes; the destination operand is a general-purpose register. The address-size and operand-size attributes affect the action performed by this instruction, as shown in the following table. The operand-size attribute of the instruction is determined by the chosen register; the address-size attribute is determined by the attribute of the code segment.

<table>
<thead>
<tr>
<th>Operand Size</th>
<th>Address Size</th>
<th>Action Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>16</td>
<td>16-bit effective address is calculated and stored in requested 16-bit register destination.</td>
</tr>

<tbody>
<tr>
<td>C9</td>
<td>LEAVE</td>
<td>Set SP to BP, then pop BP</td>
</tr>
<tr>
<td>C9</td>
<td>LEAVE</td>
<td>Set ESP to EBP, then pop EBP</td>
</tr>
</tbody>
</table>

**Description**

Releases the stack frame set up by an earlier ENTER instruction. The LEAVE instruction copies the frame pointer (in the EBP register) into the stack pointer register (ESP), which releases the stack space allocated to the stack frame. The old frame pointer (the frame pointer for the calling procedure that was saved by the ENTER instruction) is then popped from the stack into the EBP register, restoring the calling procedure’s stack frame.

A RET instruction is commonly executed following a LEAVE instruction to return program control to the calling procedure.

See “Procedure Calls for Block-Structured Languages” in Chapter 6 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1,* for detailed information on the use of the ENTER and LEAVE instructions.

**Operation**

IF StackAddressSize ← 32
   THEN
      ESP ← EBP;
      ELSE (* StackAddressSize ← 16*)
      SP ← BP;
   FI;
IF OperandSize ← 32
   THEN

#SS(0)    If the EBP register points to a location that is not within the limits of the current stack segment.

#PF(fault-code)    If a page fault occurs.
LEAVE—High Level Procedure Exit (Continued)

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If the EBP register points to a location outside of the effective address space from 0 to FFFFH.

Virtual-8086 Mode Exceptions

#GP(0) If the EBP register points to a location outside of the effective address space from 0 to FFFFH.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
LES—Load Full Pointer

See entry for LDS/LES/LFS/LGS/LSS—Load Far Pointer.
LFENCE—Load Fence

**Description**

Performs a serializing operation on all load-from-memory instructions that were issued prior the LFENCE instruction. This serializing operation guarantees that every load instruction that precedes in program order the LFENCE instruction is globally visible before any load instruction that follows the LFENCE instruction is globally visible. The LFENCE instruction is ordered with respect to load instructions, other LFENCE instructions, any MFENCE instructions, and any serializing instructions (such as the CPUID instruction). It is not ordered with respect to store instructions or the SFENCE instruction.

Weakly ordered memory types can be used to achieve higher processor performance through such techniques as out-of-order issue and speculative reads. The degree to which a consumer of data recognizes or knows that the data is weakly ordered varies among applications and may be unknown to the producer of this data. The LFENCE instruction provides a performance-efficient way of insuring load ordering between routines that produce weakly-ordered results and routines that consume that data.

It should be noted that processors are free to speculatively fetch and cache data from system memory regions that are assigned a memory-type that permits speculative reads (that is, the WB, WC, and WT memory types). The PREFETCH\(h\) instruction is considered a hint to this speculative behavior. Because this speculative fetching can occur at any time and is not tied to instruction execution, the LFENCE instruction is not ordered with respect to PREFETCH\(h\) instructions or any other speculative fetching mechanism (that is, data could be speculative loaded into the cache just before, during, or after the execution of an LFENCE instruction).

**Operation**

\[
\text{Wait\_On\_Following\_Loads\_Until}(\text{preceding\_loads\_globally\_visible});
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

```c
void_mm_lfence(void)
```

**Exceptions (All Modes of Operation)**

None.
LFS—Load Full Pointer

LGDT/LIDT—Load Global/Interrupt Descriptor Table Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 01 /2</td>
<td>LGDT m16&amp;32</td>
<td>Load m into GDTR</td>
</tr>
<tr>
<td>0F 01 /3</td>
<td>LIDT m16&amp;32</td>
<td>Load m into IDTR</td>
</tr>
</tbody>
</table>

**Description**

Loads the values in the source operand into the global descriptor table register (GDTR) or the interrupt descriptor table register (IDTR). The source operand specifies a 6-byte memory location that contains the base address (a linear address) and the limit (size of table in bytes) of the global descriptor table (GDT) or the interrupt descriptor table (IDT). If operand-size attribute is 32 bits, a 16-bit limit (lower 2 bytes of the 6-byte data operand) and a 32-bit base address (upper 4 bytes of the data operand) are loaded into the register. If the operand-size attribute is 16 bits, a 16-bit limit (lower 2 bytes) and a 24-bit base address (third, fourth, and fifth byte) are loaded. Here, the high-order byte of the operand is not used and the high-order byte of the base address in the GDTR or IDTR is filled with zeros.

The LGDT and LIDT instructions are used only in operating-system software; they are not used in application programs. They are the only instructions that directly load a linear address (that is, not a segment-relative address) and a limit in protected mode. They are commonly executed in real-address mode to allow processor initialization prior to switching to protected mode.

See “SFENCE—Store Fence” in this chapter for information on storing the contents of the GDTR and IDTR.

LGS—Load Full Pointer

See entry for LDS/LES/LFS/LGS/LSS—Load Far Pointer.
LLDT—Load Local Descriptor Table Register

Description
Loads the source operand into the segment selector field of the local descriptor table register (LDTR). The source operand (a general-purpose register or a memory location) contains a segment selector that points to a local descriptor table (LDT). After the segment selector is loaded in the LDTR, the processor uses the segment selector to locate the segment descriptor for the LDT in the global descriptor table (GDT). It then loads the segment limit and base address for the LDT from the segment descriptor into the LDTR. The segment registers DS, ES, SS, FS, GS, and CS are not affected by this instruction, nor is the LDTR field in the task state segment (TSS) for the current task.

If the source operand is 0, the LDTR is marked invalid and all references to descriptors in the LDT (except by the LAR, VERR, VERW or LSL instructions) cause a general protection exception (#GP).

The operand-size attribute has no effect on this instruction.

The LLDT instruction is provided for use in operating-system software; it should not be used in application programs. Also, this instruction can only be executed in protected mode.

Operation
IF SRC[Offset] > descriptor table limit THEN #GP(segment selector); FI;
Read segment descriptor;
IF SegmentDescriptor(Type) ≠ LDT THEN #GP(segment selector); FI;
IF segment descriptor is not present THEN #NP(segment selector);
LDTR(SegmentSelector) ← SRC;

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#GP(selector) If the selector operand does not point into the Global Descriptor Table or if the entry in the GDT is not a Local Descriptor Table.
LLDT—Load Local Descriptor Table Register (Continued)

Segment selector is beyond GDT limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NP(selector) If the LDT descriptor is not present.

#PF(fault-code) If a page fault occurs.

Real-Address Mode Exceptions

#UD The LLDT instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD The LLDT instruction is recognized in virtual-8086 mode.
LIDT—Load Interrupt Descriptor Table Register

See entry for LGDT/LIDT—Load Global/Interrupt Descriptor Table Register.
LMSW—Load Machine Status Word

**Description**

Loads the source operand into the machine status word, bits 0 through 15 of register CR0. The source operand can be a 16-bit general-purpose register or a memory location. Only the low-order 4 bits of the source operand (which contains the PE, MP, EM, and TS flags) are loaded into CR0. The PG, CD, NW, AM, WP, NE, and ET flags of CR0 are not affected. The operand-size attribute has no effect on this instruction.

If the PE flag of the source operand (bit 0) is set to 1, the instruction causes the processor to switch to protected mode. While in protected mode, the LMSW instruction cannot be used clear the PE flag and force a switch back to real-address mode.

The LMSW instruction is provided for use in operating-system software; it should not be used in application programs. In protected or virtual-8086 mode, it can only be executed at CPL 0.

This instruction is provided for compatibility with the Intel 286™ processor; programs and procedures intended to run on the Pentium 4, P6 family, Pentium, Intel486, and Intel386 processors should use the MOV (control registers) instruction to load the whole CR0 register. The MOV CR0 instruction can be used to set and clear the PE flag in CR0, allowing a procedure or program to switch between protected and real-address modes.

This instruction is a serializing instruction.

**Operation**

\[
\text{CR0}[0:3] \leftarrow \text{SRC}[0:3];
\]

**Flags Affected**

None.

**Protected Mode Exceptions**

- **#GP(0)**  
  If the current privilege level is not 0.
  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

- **#SS(0)**  
  If a memory operand effective address is outside the SS segment limit.

- **#PF(fault-code)**  
  If a page fault occurs.
LMSW—Load Machine Status Word (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If the current privilege level is not 0.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
LOCK—Assert LOCK# Signal Prefix

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>LOCK</td>
<td>Asserts LOCK# signal for duration of the accompanying instruction</td>
</tr>
</tbody>
</table>

**Description**

Causes the processor’s LOCK# signal to be asserted during execution of the accompanying instruction (turns the instruction into an atomic instruction). In a multiprocessor environment, the LOCK# signal insures that the processor has exclusive use of any shared memory while the signal is asserted.

Note that in later IA-32 processors (such as the Pentium Pro processor), locking may occur without the LOCK# signal being asserted. See IA-32 Architecture Compatibility below.

The LOCK prefix can be prepended only to the following instructions and only to those forms of the instructions where the destination operand is a memory operand: ADD, ADC, AND, BTC, BTR, BTS, CMPXCHG, CMPXCH8B, DEC, INC, NEG, NOT, OR, SBB, SUB, XOR, XADD, and XCHG. If the LOCK prefix is used with one of these instructions and the source operand is a memory operand, an undefined opcode exception (#UD) may be generated. An undefined opcode exception will be generated if the LOCK prefix is used with any instruction not in the above list. The XCHG instruction always asserts the LOCK# signal regardless of the presence or absence of the LOCK prefix.

The LOCK prefix is typically used with the BTS instruction to perform a read-modify-write operation on a memory location in shared memory environment.

The integrity of the LOCK prefix is not affected by the alignment of the memory field. Memory locking is observed for arbitrarily misaligned fields.

**IA-32 Architecture Compatibility**

Beginning with the Pentium Pro processor, when the LOCK prefix is prefixed to an instruction and the memory area being accessed is cached internally in the processor, the LOCK# signal is generally not asserted. Instead, only the processor’s cache is locked. Here, the processor’s cache coherency mechanism insures that the operation is carried out atomically with regards to memory. See “Effects of a Locked Operation on Internal Processor Caches” in Chapter 7 of *IA-32 Intel Architecture Software Developer’s Manual, Volume 3*, for more information on locking of caches.

**Operation**

AssertLOCK#(DurationOfAccompanyingInstruction)

**Flags Affected**

None.
LOCK—Assert LOCK# Signal Prefix (Continued)

Protected Mode Exceptions

<td>LODSW</td>
<td>Load word at address DS:(E)SI into AX</td>
</tr>
<tr>
<td>AD</td>
<td>LODSD</td>
<td>Load doubleword at address DS:(E)SI into EAX</td>
</tr>
</tbody>
</table>

**Description**

Loads a byte, word, or doubleword from the source operand into the AL, AX, or EAX register, respectively. The source operand is a memory location, the address of which is read from the DS:EDI or the DS:SI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). The DS segment may be overridden with a segment override prefix.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the LODS mnemonic) allows the source operand to be specified explicitly. Here, the source operand should be a symbol that indicates the size and location of the source value. The destination operand is then automatically selected to match the size of the source operand (the AL register for byte operands, AX for word operands, and EAX for doubleword operands). This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the source operand symbol must specify the correct type (size) of the operand (byte, word, or doubleword), but it does not have to specify the correct location. The location is always specified by the DS:(E)SI registers, which must be loaded correctly before the load string instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the LODS instructions. Here also DS:(E)SI is assumed to be the source operand and the AL, AX, or EAX register is assumed to be the destination operand. The size of the source and destination operands is selected with the mnemonic: LODSB (byte loaded into register AL), LODSW (word loaded into AX), or LODSD (doubleword loaded into EAX).

After the byte, word, or doubleword is transferred from the memory location into the AL, AX, or EAX register, the (E)SI register is incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)SI register is incremented; if the DF flag is 1, the ESI register is decremented.) The (E)SI register is incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.

The LODS, LODSB, LODSW, and LODSD instructions can be preceded by the REP prefix for block loads of ECX bytes, words, or doublewords. More often, however, these instructions are used within a LOOP construct because further processing of the data moved into the register is usually necessary before the next transfer can be made. See “REP/REPE/REPZ/REPNE/REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.

</tr>
<tr>
<td>E0 cb</td>
<td>LOOPNZ rel8</td>
<td>Decrement count; jump short if count ≠ 0 and ZF=0</td>
</tr>
</tbody>
</table>

Description

Performs a loop operation using the ECX or CX register as a counter. Each time the LOOP instruction is executed, the count register is decremented, then checked for 0. If the count is 0, the loop is terminated and program execution continues with the instruction following the LOOP instruction. If the count is not zero, a near jump is performed to the destination (target) operand, which is presumably the instruction at the beginning of the loop. If the address-size attribute is 32 bits, the ECX register is used as the count register; otherwise the CX register is used.

The target instruction is specified with a relative offset (a signed offset relative to the current value of the instruction pointer in the EIP register). This offset is generally specified as a label in assembly code, but at the machine code level, it is encoded as a signed, 8-bit immediate value, which is added to the instruction pointer. Offsets of –128 to +127 are allowed with this instruction.

Some forms of the loop instruction (LOOPcc) also accept the ZF flag as a condition for terminating the loop before the count reaches zero. With these forms of the instruction, a condition code (cc) is associated with each instruction to indicate the condition being tested for. Here, the LOOPcc instruction itself does not affect the state of the ZF flag; the ZF flag is changed by other instructions in the loop.

Operation

IF AddressSize ← 32

</tr>
<tr>
<td>0F 03 /r</td>
<td>LSL r32,r/m32</td>
<td>Load: r32 ← segment limit, selector r/m32</td>
</tr>
</tbody>
</table>

Description

Loads the unscrambled segment limit from the segment descriptor specified with the second operand (source operand) into the first operand (destination operand) and sets the ZF flag in the EFLAGS register. The source operand (which can be a register or a memory location) contains the segment selector for the segment descriptor being accessed. The destination operand is a general-purpose register.

The processor performs access checks as part of the loading process. Once loaded in the destination register, software can compare the segment limit with the offset of a pointer.

The segment limit is a 20-bit value contained in bytes 0 and 1 and in the first 4 bits of byte 6 of the segment descriptor. If the descriptor has a byte granular segment limit (the granularity flag is set to 0), the destination operand is loaded with a byte granular value (byte limit). If the descriptor has a page granular segment limit (the granularity flag is set to 1), the LSL instruction will translate the page granular limit (page limit) into a byte limit before loading it into the destination operand. The translation is performed by shifting the 20-bit “raw” limit left 12 bits and filling the low-order 12 bits with 1s.

When the operand size is 32 bits, the 32-bit byte limit is stored in the destination operand. When the operand size is 16 bits, a valid 32-bit limit is computed; however, the upper 16 bits are truncated and only the low-order 16 bits are loaded into the destination operand.

This instruction performs the following checks before it loads the segment limit into the destination register:

- Checks that the segment selector is not null.
- Checks that the segment selector points to a descriptor that is within the limits of the GDT or LDT being accessed.
- Checks that the descriptor type is valid for this instruction. All code and data segment descriptors are valid for (can be accessed with) the LSL instruction. The valid special segment and gate descriptor types are given in the following table.
- If the segment is not a conforming code segment, the instruction checks that the specified segment descriptor is visible at the CPL (that is, if the CPL and the RPL of the segment selector are less than or equal to the DPL of the segment selector).

If the segment descriptor cannot be accessed or is an invalid type for the instruction, the ZF flag is cleared and no value is loaded in the destination operand.

```

Flags Affected
The ZF flag is set to 1 if the segment limit is loaded successfully; otherwise, it is cleared to 0.

Protected Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#UD The LSL instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions
#UD The LSL instruction is not recognized in virtual-8086 mode.
LSS—Load Full Pointer

See entry for LDS/LES/LFS/LGS/LSS—Load Far Pointer.
LTR—Load Task Register

Description

Loads the source operand into the segment selector field of the task register. The source operand (a general-purpose register or a memory location) contains a segment selector that points to a task state segment (TSS). After the segment selector is loaded in the task register, the processor uses the segment selector to locate the segment descriptor for the TSS in the global descriptor table (GDT). It then loads the segment limit and base address for the TSS from the segment descriptor into the task register. The task pointed to by the task register is marked busy, but a switch to the task does not occur.

The LTR instruction is provided for use in operating-system software; it should not be used in application programs. It can only be executed in protected mode when the CPL is 0. It is commonly used in initialization code to establish the first task to be executed.

The operand-size attribute has no effect on this instruction.

Operation

IF SRC[Offset] > descriptor table limit OR IF SRC[type] ≠ global
THEN #GP(segment selector);
FI;
Read segment descriptor;
IF segment descriptor is not for an available TSS THEN #GP(segment selector); FI;
IF segment descriptor is not present THEN #NP(segment selector);
TSSSegmentDescriptor(busy) ← 1;
("Locked read-modify-write operation on the entire descriptor when setting busy flag")
TaskRegister(SegmentSelector) ← SRC;
TaskRegister(SegmentDescriptor) ← TSSSegmentDescriptor;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.
LTR—Load Task Register (Continued)

#GP(selector)  If the source selector points to a segment that is not a TSS or to one for a task that is already busy.
   If the selector points to LDT or is beyond the GDT limit.

#NP(selector)  If the TSS is marked not present.

#SS(0)  If a memory operand effective address is outside the SS segment limit.

#PF(fault-code)  If a page fault occurs.

Real-Address Mode Exceptions

#UD  The LTR instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD  The LTR instruction is not recognized in virtual-8086 mode.
MASKMOVDQU—Store Selected Bytes of Double Quadword

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F F7 /r</td>
<td>MASKMOVDQU xmm1, xmm2</td>
<td>Selectively write bytes from xmm1 to memory location using the byte mask in xmm2.</td>
</tr>
</tbody>
</table>

**Description**
Stores selected bytes from the source operand (first operand) into an 128-bit memory location. The mask operand (second operand) selects which bytes from the source operand are written to memory. The source and mask operands are XMM registers. The location of the first byte of the memory location is specified by DI/EDI and DS registers. The memory location does not need to be aligned on a natural boundary. (The size of the store address depends on the address-size attribute.)

The most significant bit in each byte of the mask operand determines whether the corresponding byte in the source operand is written to the corresponding byte location in memory: 0 indicates no write and 1 indicates write.

The MASKMOVDQU instruction generates a non-temporal hint to the processor to minimize cache pollution. The non-temporal hint is implemented by using a write combining (WC) memory type protocol (see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10, of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MASKMOVDQU instructions if multiple processors might use different memory types to read/write the destination memory locations.

Behavior with a mask of all 0s is as follows:
- No data will be written to memory.
- Signaling of breakpoints (code or data) is not guaranteed; different processor implementations may signal or not signal these breakpoints.
- Exceptions associated with addressing memory and page faults may still be signaled (implementation dependent).
- If the destination memory region is mapped as UC or WP, enforcement of associated semantics for these memory types is not guaranteed (that is, is reserved) and is implementation-specific.

The MASKMOVDQU instruction can be used to improve performance of algorithms that need to merge data on a byte-by-byte basis. MASKMOVDQU should not cause a read for ownership; doing so generates unnecessary bandwidth since data is to be written directly using the byte-mask without allocating old data prior to the store.

MASKMOVQ—Store Selected Bytes of Quadword

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F F7 /r</td>
<td>MASKMOVQ mm1, mm2</td>
<td>Selectively write bytes from mm1 to memory location using the byte mask in mm2</td>
</tr>
</tbody>
</table>

**Description**

Stores selected bytes from the source operand (first operand) into a 64-bit memory location. The mask operand (second operand) selects which bytes from the source operand are written to memory. The source and mask operands are MMX registers. The location of the first byte of the memory location is specified by DI/EDI and DS registers. (The size of the store address depends on the address-size attribute.)

The most significant bit in each byte of the mask operand determines whether the corresponding byte in the source operand is written to the corresponding byte location in memory: 0 indicates no write and 1 indicates write.

The MASKMOVQ instruction generates a non-temporal hint to the processor to minimize cache pollution. The non-temporal hint is implemented by using a write combining (WC) memory type protocol (see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10, of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MASKMOVEDQ instructions if multiple processors might use different memory types to read/write the destination memory locations.

This instruction causes a transition from x87 FPU to MMX state (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]).

The behavior of the MASKMOVQ instruction with a mask of all 0s is as follows:

- No data will be written to memory.
- Transition from x87 FPU to MMX state will occur.
- Exceptions associated with addressing memory and page faults may still be signaled (implementation dependent).
- Signaling of breakpoints (code or data) is not guaranteed (implementations dependent).
- If the destination memory region is mapped as UC or WP, enforcement of associated semantics for these memory types is not guaranteed (that is, is reserved) and is implementation-specific.

The MASKMOVQ instruction can be used to improve performance for algorithms that need to merge data on a byte-by-byte basis. It should not cause a read for ownership; doing so generates unnecessary bandwidth since data is to be written directly using the byte-mask without allocating old data prior to the store.

MAXPD—Return Maximum Packed Double-Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 5F /r</td>
<td>MAXPD xmm1, xmm2/m128</td>
<td>Return the maximum double-precision floating-point values between xmm2/m128 and xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Performs a SIMD compare of the packed double-precision floating-point values in the destination operand (first operand) and the source operand (second operand), and returns the maximum value for each pair of values to the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register.

If the values being compared are both 0.0s, the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is forwarded unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. This behavior allows compilers to use the MAXPD instruction for common C conditional constructs. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of the MAXPD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

**Operation**

#PF(fault-code) For a page fault.
MAXSD—Return Maximum Scalar Double-Precision Floating-Point Value

Description

Compares the low double-precision floating-point values in the destination operand (first operand) and the source operand (second operand), and returns the maximum value to the low quadword of the destination operand. The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. When the source operand is a memory operand, only 64 bits are accessed. The high quadword of the destination operand remains unchanged.

If the values being compared are both 0.0s, the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is returned unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. This behavior allows compilers to use the MAXSD instruction for common C conditional constructs. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of the MAXSD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

MAXSS—Return Maximum Scalar Single-Precision Floating-Point Value

Description

Compares the low single-precision floating-point values in the destination operand (first operand) and the source operand (second operand), and returns the maximum value to the low doubleword of the destination operand. The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. When the source operand is a memory operand, only 32 bits are accessed. The three high-order doublewords of the destination operand remain unchanged.

If the values being compared are both 0.0s, the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is returned unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. This behavior allows compilers to use the MAXSS instruction for common C conditional constructs. MFENCE—Memory Fence

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F AE /6</td>
<td>MFENCE</td>
<td>Serializes load and store operations.</td>
</tr>
</tbody>
</table>

**Description**

Performs a serializing operation on all load-from-memory and store-to-memory instructions that were issued prior the MFENCE instruction. This serializing operation guarantees that every load and store instruction that precedes in program order the MFENCE instruction is globally visible before any load or store instruction that follows the MFENCE instruction is globally visible. The MFENCE instruction is ordered with respect to all load and store instructions, other MFENCE instructions, any SFENCE and LFENCE instructions, and any serializing instructions (such as the CPUID instruction).

Weakly ordered memory types can be used to achieve higher processor performance through such techniques as out-of-order issue, speculative reads, write-combining, and write-collapsing. The degree to which a consumer of data recognizes or knows that the data is weakly ordered varies among applications and may be unknown to the producer of this data. The MFENCE instruction provides a performance-efficient way of ensuring load and store ordering between routines that produce weakly-ordered results and routines that consume that data.

It should be noted that processors are free to speculatively fetch and cache data from system memory regions that are assigned a memory-type that permits speculative reads (that is, the WB, WC, and WT memory types). The PREFETCHh instruction is considered a hint to this speculative behavior. Because this speculative fetching can occur at any time and is not tied to instruction execution, the MFENCE instruction is not ordered with respect to PREFETCHh instructions or any other speculative fetching mechanism (that is, data could be speculative loaded into the cache just before, during, or after the execution of an MFENCE instruction).

**Operation**

Wait_On_Following_Loads_And_Stores_Until(preceding_loads_and_stores_globally_visible);

MINPD—Return Minimum Packed Double-Precision Floating-Point Values

**Description**

Performs a SIMD compare of the packed double-precision floating-point values in the destination operand (first operand) and the source operand (second operand), and returns the minimum value for each pair of values to the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register.

If the values being compared are both 0.0s, the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is returned unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. This behavior allows compilers to use the MINPD instruction for common C conditional constructs. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of the MINPD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

INSTRUCTION SET REFERENCE

MINSD—Return Minimum Scalar Double-Precision Floating-Point Value

Description

Compares the low double-precision floating-point values in the destination operand (first operand) and the source operand (second operand), and returns the minimum value to the low quadword of the destination operand. The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. When the source operand is a memory operand, only the 64 bits are accessed. The high quadword of the destination operand remains unchanged.

If the values being compared are both 0.0s, the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is returned unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. This behavior allows compilers to use the MINSD instruction for common C conditional constructs. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of the MINSD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

Operation

NOTES:
* The moffs8, moffs16, and moffs32 operands specify a simple offset relative to the segment base, where 8, 16, and 32 refer to the size of the data. The address-size attribute of the instruction determines the size of the offset, either 16 or 32 bits.
** In 32-bit mode, the assembler may insert the 16-bit operand-size prefix with this instruction (see the following “Description” section for further information).

Description
Copies the second operand (source operand) to the first operand (destination operand). The source operand can be an immediate value, general-purpose register, segment register, or memory location; the destination register can be a general-purpose register, segment register, or memory location. Both operands must be the same size, which can be a byte, a word, or a doubleword.

The MOV instruction cannot be used to load the CS register. Attempting to do so results in an invalid opcode exception (#UD). To load the CS register, use the far JMP, CALL, or RET instruction.
MOV—Move (Continued)

If the destination operand is a segment register (DS, ES, FS, GS, or SS), the source operand must be a valid segment selector. In protected mode, moving a segment selector into a segment register automatically causes the segment descriptor information associated with that segment selector to be loaded into the hidden (shadow) part of the segment register. While loading this information, the segment selector and segment descriptor information is validated (see the “Operation” algorithm below). The segment descriptor data is obtained from the GDT or LDT entry for the specified segment selector.

A null segment selector (values 0000-0003) can be loaded into the DS, ES, FS, and GS registers without causing a protection exception. However, any subsequent attempt to reference a segment whose corresponding segment register is loaded with a null value causes a general protection exception (#GP) and no memory reference occurs.

Loading the SS register with a MOV instruction inhibits all interrupts until after the execution of the next instruction. This operation allows a stack pointer to be loaded into the ESP register with the next instruction (MOV ESP, stack-pointer value) before an interrupt occurs. The LSS instruction offers a more efficient method of loading the SS and ESP registers.

When operating in 32-bit mode and moving data between a segment register and a general-purpose register, the 32-bit IA-32 processors do not require the use of the 16-bit operand-size prefix (a byte with the value 66H) with this instruction, but most assemblers will insert it if the standard form of the instruction is used (for example, MOV DS, AX). The processor will execute this instruction correctly, but it will usually require an extra clock. With most assemblers, using the instruction form MOV DS, EAX will avoid this unneeded 66H prefix. When the processor executes the instruction with a 32-bit general-purpose register, it assumes that the 16 least-significant bits of the general-purpose register are the destination or source operand. If the register is a destination operand, the resulting value in the two high-order bytes of the register is implementation dependent. For the Pentium Pro processor, the two high-order bytes are filled with zeros; for earlier 32-bit IA-32 processors, the two high order bytes are undefined.

Operation

\[ \text{DEST} \leftarrow \text{SRC}; \]

Loading a segment register while in protected mode results in special checks and actions, as described in the following listing. These checks are performed on the segment selector and the segment descriptor it points to.

IF SS is loaded;

________________________________________________________________________

1. Note that in a sequence of instructions that individually delay interrupts past the following instruction, only the first instruction in the sequence is guaranteed to delay the interrupt, but subsequent interrupt-delaying instructions may not delay the interrupt. Thus, in the following instruction sequence:

\[ \begin{align*}
\text{STI} \\
\text{MOV SS, EAX} \\
\text{MOV ESP, EBP}
\end{align*} \]

interrupts may be recognized before MOV ESP, EBP executes, because STI also delays interrupts for one instruction.

</tbody>
</table>

Description

Moves the contents of a control register (CR0, CR2, CR3, or CR4) to a general-purpose register or vice versa. The operand size for these instructions is always 32 bits, regardless of the operand-size attribute. (See “Control Registers” in Chapter 2 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for a detailed description of the flags and fields in the control registers.) This instruction can be executed only when the current privilege level is 0.

When loading a control register, a program should not attempt to change any of the reserved bits; that is, always set reserved bits to the value previously read.

At the opcode level, the reg field within the ModR/M byte specifies which of the control registers is loaded or read. The 2 bits in the mod field are always 11B. The r/m field specifies the general-purpose register loaded or read.

These instructions have the following side effects:

- When writing to control register CR3, all non-global TLB entries are flushed (see “Translation Lookaside Buffers (TLBs)” in Chapter 3 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3).

The following side effects are implementation specific for the Pentium Pro processors. Software should not depend on this functionality in future and previous IA-32 processors:

- When modifying any of the paging flags in the control registers (PE and PG in register CR0 and PGE, PSE, and PAE in register CR4), all TLB entries are flushed, including global entries.
- If the PG flag is set to 1 and control register CR4 is written to set the PAE flag to 1 (to enable the physical address extension mode), the pointers (PDPTRs) in the page-directory pointers table will be loaded into the processor (into internal, non-architectural registers).
- If the PAE flag is set to 1 and the PG flag set to 1, writing to control register CR3 will cause the PDPTRs to be reloaded into the processor.
- If the PAE flag is set to 1 and control register CR0 is written to set the PG flag, the PDPTRs are reloaded into the processor.
MOV—Move to/from Control Registers (Continued)

Operation
DEST ← SRC;

Flags Affected
The OF, SF, ZF, AF, PF, and CF flags are undefined.

Protected Mode Exceptions
#GP(0) If the current privilege level is not 0.
If an attempt is made to write invalid bit combinations in CR0 (such as setting the PG flag to 1 when the PE flag is set to 0, or setting the CD flag to 0 when the NW flag is set to 1).
If an attempt is made to write a 1 to any reserved bit in CR4.

Real-Address Mode Exceptions
#GP If an attempt is made to write a 1 to any reserved bit in CR4.

Virtual-8086 Mode Exceptions
#GP(0) These instructions cannot be executed in virtual-8086 mode.
MOV—Move to/from Debug Registers

Description

Moves the contents of a debug register (DR0, DR1, DR2, DR3, DR4, DR5, DR6, or DR7) to a
general-purpose register or vice versa. The operand size for these instructions is always 32 bits,
regardless of the operand-size attribute. (See Chapter 14, Debugging and Performance Moni-
toring, of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for a detailed
description of the flags and fields in the debug registers.)

The instructions must be executed at privilege level 0 or in real-address mode.

When the debug extension (DE) flag in register CR4 is clear, these instructions operate on debug
registers in a manner that is compatible with Intel386 and Intel486 processors. In this mode,
references to DR4 and DR5 refer to DR6 and DR7, respectively. When the DE set in CR4 is set,
attempts to reference DR4 and DR5 result in an undefined opcode (#UD) exception. (The CR4
register was added to the IA-32 Architecture beginning with the Pentium processor.)

At the opcode level, the reg field within the ModR/M byte specifies which of the debug registers
is loaded or read. The two bits in the mod field are always 11. The r/m field specifies the general-
purpose register loaded or read.

Operation

IF ((DE ← 1) and (SRC or DEST ← DR4 or DR5))
THEN
#UD;
ELSE
DEST ← SRC;

Flags Affected

The OF, SF, ZF, AF, PF, and CF flags are undefined.

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.

#UD If the DE (debug extensions) bit of CR4 is set and a MOV instruction is executed involving DR4 or DR5.

#DB If any debug register is accessed while the GD flag in debug register DR7
is set.
MOV—Move to/from Debug Registers (Continued)

Real-Address Mode Exceptions

#UD If the DE (debug extensions) bit of CR4 is set and a MOV instruction is executed involving DR4 or DR5.

#DB If any debug register is accessed while the GD flag in debug register DR7 is set.

Virtual-8086 Mode Exceptions

#GP(0) The debug registers cannot be loaded or read when in virtual-8086 mode.
MOVAPD—Move Aligned Packed Double-Precision Floating-Point Values

<td>MOVAPD xmm2/m128, xmm1</td>
<td>Move packed double-precision floating-point values from xmm1 to xmm2/m128.</td>
</tr>
</tbody>
</table>

Description

Moves a double quadword containing two packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) will be generated.

To move double-precision floating-point values to and from unaligned memory locations, use the MOVUPD instruction.

Operation

DEST ← SRC;

<td>MOVAPS xmm2/m128, xmm1</td>
<td>Move packed single-precision floating-point values from xmm1 to xmm2/m128.</td>
</tr>
</tbody>
</table>

**Description**

Moves a double quadword containing four packed single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) is generated.

To move packed single-precision floating-point values to or from unaligned memory locations, use the MOVUPS instruction.

**Operation**

DEST ← SRC;

**Intel C/C++ Compiler Intrinsic Equivalent**

```c
__m128 _mm_load_ps (float * p)
void _mm_store_ps (float *p, __m128 a)
```

**SIMD Floating-Point Exceptions**

None.

**Protected Mode Exceptions**

- **#GP(0)** For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
  
  If memory operand is not aligned on a 16-byte boundary, regardless of segment.
- **#SS(0)** For an illegal address in the SS segment.
- **#PF(fault-code)** For a page fault.
- **#NM** If TS in CR0 is set.

#NM  If TS in CR0 is set.
#XM  If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
#UD  If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
     If EM in CR0 is set.
     If OSFXSR in CR4 is 0.
     If CPUID feature flag SSE2 is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code)  For a page fault.
MOVD—Move Doubleword

Description
Copies a doubleword from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be general-purpose registers, MMX registers, XMM registers, or 32-bit memory locations. This instruction can be used to move a doubleword to and from the low doubleword an MMX register and a general-purpose register or a 32-bit memory location, or to and from the low doubleword of an XMM register and a general-purpose register or a 32-bit memory location. The instruction cannot be used to transfer data between MMX registers, between XMM registers, between general-purpose registers, or between memory locations.

When the destination operand is an MMX register, the source operand is written to the low doubleword of the register, and the register is zero-extended to 64 bits. When the destination operand is an XMM register, the source operand is written to the low doubleword of the register, and the register is zero-extended to 128 bits.

Operation
MOVD instruction when destination operand is MMX register:
DEST[31-0] ← SRC;
DEST[63-32] ← 00000000H;

MOVD instruction when destination operand is XMM register:
DEST[31-0] ← SRC;
DEST[127-32] ← 000000000000000000000000H;

MOVD instruction when source operand is MMX or XMM register:
DEST ← SRC[31-0];

Intel C/C++ Compiler Intrinsic Equivalent
MOVD __m64 _mm_cvtsi32_si64 (int i )
MOVD int _mm_cvtsi64_si32 ( __m64m )
MOVD __m128i __mm_cvtsi32_si128 (int a)
MOVD int _mm_cvtsi128_si32 ( __m128i a)

Flags Affected
None.
INSTRUCTION SET REFERENCE

<tr>
<td>66 0F 7F /r</td>
<td>MOVDQA xmm2/m128, xmm1</td>
<td>Move aligned double quadword from xmm1 to xmm2/m128.</td>
</tr>
</tbody>
</table>

Description

Moves a double quadword from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) will be generated.

To move a double quadword to or from unaligned memory locations, use the MOVDQU instruction.

Operation

DEST ← SRC;
* #GP if SRC or DEST unaligned memory operand *;

Intel C/C++ Compiler Intrinsic Equivalent

MOVDQA __m128i _mm_load_si128 ( __m128i *p)
MOVDQA void _mm_store_si128 ( __m128i *p, __m128i a)

SIMD Floating-Point Exceptions

None.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If memory operand is not aligned on a 16-byte boundary, regardless of segment.

   If OSFXSR in CR4 is 0.
   If CPUID feature flag SSE2 is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
MOVDQU—Move Unaligned Double Quadword

Description

Moves a double quadword from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand may be unaligned on a 16-byte boundary without causing a general-protection exception (#GP) to be generated.

To move a double quadword to or from memory locations that are known to be aligned on 16-byte boundaries, use the MOVDQA instruction.

While executing in 16-bit addressing mode, a linear address for a 128-bit data access that overlaps the end of a 16-bit segment is not allowed and is defined as reserved behavior. A specific processor implementation may or may not generate a general-protection exception (#GP) in this situation, and the address that spans the end of the segment may or may not wrap around to the beginning of the segment.

Operation

DEST ← SRC;

Intel C/C++ Compiler Intrinsic Equivalent

MOVDQU void _mm_storeu_si128 ( __m128i *p, __m128i a)
MOVDQU __m128i _mm_loadu_si128 ( __m128i *p)

SIMD Floating-Point Exceptions

None.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#NM If TS in CR0 is set.

MOVDQ2Q—Move Quadword from XMM to MMX Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2 0F D6</td>
<td>MOVDQ2Q mm, xmm</td>
<td>Move low quadword from xmm to mmx register</td>
</tr>
</tbody>
</table>

**Description**

Moves the low quadword from the source operand (second operand) to the destination operand (first operand). The source operand is an XMM register and the destination operand is an MMX register.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the MOVDQ2Q instruction is executed.

**Operation**

\[
\text{DEST} \leftarrow \text{SRC}[63-0]
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

MOVDQ2Q _m64 _mm_movepi64_pi64 ( _m128i a)

**SIMD Floating-Point Exceptions**

None.

**Protected Mode Exceptions**

- #NM If TS in CR0 is set.

MOVHLPS—Move Packed Single-Precision Floating-Point Values High to Low

**Description**
Moves two packed single-precision floating-point values from the high quadword of the source operand (second operand) to the low quadword of the destination operand (first operand). The high quadword of the destination operand is left unchanged.

**Operation**

DEST[63:0] ← SRC[127-64];
* DEST[127-64] unchanged *;

**Intel C/C++ Compiler Intrinsic Equivalent**

MOVHLPS __m128 _mm_movehl_ps(__m128 a, __m128 b)

**SIMD Floating-Point Exceptions**
None.

**Protected Mode Exceptions**

#NM If TS in CR0 is set.

#UD If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

**Real Address Mode Exceptions**
Same exceptions as in Protected Mode.

**Virtual 8086 Mode Exceptions**
Same exceptions as in Protected Mode.
MOVHPD—Move High Packed Double-Precision Floating-Point Value

Description
Moves a double-precision floating-point value from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be an XMM register or a 64-bit memory location. This instruction allows a double-precision floating-point value to be moved to and from the high quadword of an XMM register and memory. It cannot be used for register to register or memory to memory moves. When the destination operand is an XMM register, the low quadword of the register remains unchanged.

Operation
MOVHPD instruction for memory to XMM move:
DEST[127-64] ← SRC ;
* DEST[63-0] unchanged *;

MOVHPD instruction for XMM to memory move:
DEST ← SRC[127-64] ;

Intel C/C++ Compiler Intrinsic Equivalent
MOVHPD __m128d _mm_loadh_pd ( __m128d a, double *p)
MOVHPD void _mm_storeh_pd (double *p, __m128d a)

SIMD Floating-Point Exceptions
None.

Protected Mode Exceptions
#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
#SS(0) For an illegal address in the SS segment.
#PF(fault-code) For a page fault.
#NM If TS in CR0 is set.

MOVHPS—Move High Packed Single-Precision Floating-Point Values

Description
Moves two packed single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be an XMM register or a 64-bit memory location. This instruction allows two single-precision floating-point values to be moved to and from the high quadword of an XMM register and memory. It cannot be used for register to register or memory to memory moves. When the destination operand is an XMM register, the low quadword of the register remains unchanged.

Operation
MOVHPD instruction for memory to XMM move:
DEST[127-64] ← SRC ;
* DEST[63-0] unchanged *;

MOVHPD instruction for XMM to memory move:
DEST ← SRC[127-64] ;

Intel C/C++ Compiler Intrinsic Equivalent

MOVNTDQ—Store Double Quadword Using Non-Temporal Hint

**Description**

Moves the double quadword in the source operand (second operand) to the destination operand (first operand) using a non-temporal hint to prevent caching of the data during the write to memory. The source operand is an XMM register, which is assumed to contain integer data (packed bytes, words, doublewords, or quadwords). The destination operand is a 128-bit memory location.

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when writing the data to memory. Using this protocol, the processor does not write the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being written to can override the non-temporal hint, if the memory address specified for the non-temporal store is in an uncacheable (UC) or write protected (WP) memory region. For more information on non-temporal stores, see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MOVNTDQ instructions if multiple processors might use different memory types to read/write the destination memory locations.

**Operation**

DEST ← SRC;

**Intel C/C++ Compiler Intrinsic Equivalent**

MOVNTDQ void_mm_stream_si128 ( __m128i *p, __m128i a)

**SIMD Floating-Point Exceptions**

MOVNTI—Store Doubleword Using Non-Temporal Hint

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F C3 /r</td>
<td>MOVNI m32, r32</td>
<td>Move doubleword from r32 to m32 using non-temporal hint.</td>
</tr>
</tbody>
</table>

**Description**

Moves the doubleword integer in the source operand (second operand) to the destination operand (first operand) using a non-temporal hint to minimize cache pollution during the write to memory. The source operand is a general-purpose register. The destination operand is a 32-bit memory location.

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when writing the data to memory. Using this protocol, the processor does not write the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being written to can override the non-temporal hint, if the memory address specified for the non-temporal store is in an uncacheable (UC) or write protected (WP) memory region. For more information on non-temporal stores, see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MOVNTI instructions if multiple processors might use different memory types to read/write the destination memory locations.

**Operation**

DEST ← SRC;

MOVNTQ—Store of Quadword Using Non-Temporal Hint

**Description**

Moves the quadword in the source operand (second operand) to the destination operand (first operand) using a non-temporal hint to minimize cache pollution during the write to memory. The source operand is an MMX register, which is assumed to contain packed integer data (packed bytes, words, or doublewords). The destination operand is a 64-bit memory location.

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when writing the data to memory. Using this protocol, the processor does not write the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being written to can override the non-temporal hint, if the memory address specified for the non-temporal store is in an uncacheable (UC) or write protected (WP) memory region. For more information on non-temporal stores, see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MOVNTQ instructions if multiple processors might use different memory types to read/write the destination memory locations.

**Operation**

\[
\text{DEST} \leftarrow \text{SRC};
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
MOVQ—Move Quadword

Description
Copies a quadword from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be MMX registers, XMM registers, or 64-bit memory locations. This instruction can be used to move a quadword between two MMX registers or between an MMX register and a 64-bit memory location, or to move data between two XMM registers or between an XMM register and a 64-bit memory location. The instruction cannot be used to transfer data between memory locations.

When the source operand is an XMM register, the low quadword is moved; when the destination operand is an XMM register, the quadword is stored to the low quadword of the register, and the high quadword is cleared to all 0s.

Operation
MOVQ instruction when operating on MMX registers and memory locations:
```
DEST ← SRC;
```
MOVQ instruction when source and destination operands are XMM registers:
```
DEST[63-0] ← SRC[63-0];
```
MOVQ instruction when source operand is XMM register and destination operand is memory location:
```
DEST ← SRC[63-0];
```
MOVQ instruction when source operand is memory location and destination operand is XMM register:
```
DEST[63-0] ← SRC;
DEST[127-64] ← 0000000000000000H;
```

Flags Affected
None.

SIMD Floating-Point Exceptions
None.
MOVQ—Move Quadword (Continued)

   made.
MOVQ2DQ—Move Quadword from MMX to XMM Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F3 0F D6</td>
<td>MOVQ2DQ xmm, mm</td>
<td>Move quadword from mmx to low quadword of xmm.</td>
</tr>
</tbody>
</table>

Description

Moves the quadword from the source operand (second operand) to the low quadword of the destination operand (first operand). The source operand is an MMX register and the destination operand is an XMM register.

This instruction causes a transition from x87 FPU to MMX technology operation (that is, the x87 FPU top-of-stack pointer is set to 0 and the x87 FPU tag word is set to all 0s [valid]). If this instruction is executed while an x87 FPU floating-point exception is pending, the exception is handled before the MOVQ2DQ instruction is executed.

Operation

\[
\text{DEST}[63-0] \leftarrow \text{SRC}[63-0]; \\

MOVS/MOVSB/MOVSW/MOVSD—Move Data from String to String

### Description

Moves the byte, word, or doubleword specified with the second operand (source operand) to the location specified with the first operand (destination operand). Both the source and destination operands are located in memory. The address of the source operand is read from the DS:ESI or the DS:SI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). The address of the destination operand is read from the ES:EDI or the ES:DI registers (again depending on the address-size attribute of the instruction). The DS segment may be overridden with a segment override prefix, but the ES segment cannot be overridden.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the MOVS mnemonic) allows the source and destination operands to be specified explicitly. Here, the source and destination operands should be symbols that indicate the size and location of the source value and the destination, respectively. This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the source and destination operand symbols must specify the correct type (size) of the operands (bytes, words, or doublewords), but they do not have to specify the correct location. The locations of the source and destination operands are always specified by the DS:(E)SI and ES:(E)DI registers, which must be loaded correctly before the move string instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the MOVS instructions. Here also DS:(E)SI and ES:(E)DI are assumed to be the source and destination operands, respectively. The size of the source and destination operands is selected with the mnemonic: MOVS (byte move), MOVSW (word move), or MOVSD (doubleword move).

After the move operation, the (E)SI and (E)DI registers are incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)SI and (E)DI register are incremented; if the DF flag is 1, the (E)SI and (E)DI registers are decremented.) The registers are incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.

The MOVS, MOVSB, MOVSW, and MOVSD instructions can be preceded by the REP prefix (see “REP/REPE/REPZ/REPNZ—Repeat String Operation Prefix” in this chapter) for block moves of ECX bytes, words, or doublewords.

<tr>
<td>F2 0F 11 /r</td>
<td>MOVSD xmm2/m64, xmm</td>
<td>Move scalar double-precision floating-point value from xmm1 register to xmm2/m64.</td>
</tr>
</tbody>
</table>

Description

Moves a scalar double-precision floating-point value from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be XMM registers or 64-bit memory locations. This instruction can be used to move a double-precision floating-point value to and from the low quadword of an XMM register and a 64-bit memory location, or to move a double-precision floating-point value between the low quadwords of two XMM registers. The instruction cannot be used to transfer data between memory locations.

When the source and destination operands are XMM registers, the high quadword of the destination operand remains unchanged. When the source operand is a memory location and destination operand is an XMM register, the high quadword of the destination operand is cleared to all 0s.

Operation

**MOVSD instruction when source and destination operands are XMM registers:**

\[
\text{DEST}[63-0] \leftarrow \text{SRC}[63-0]; \\
* \text{DEST}[127-64] \text{remains unchanged}; *
\]

**MOVSD instruction when source operand is XMM register and destination operand is memory location:**

\[
\text{DEST} \leftarrow \text{SRC}[63-0];
\]

**MOVSD instruction when source operand is memory location and destination operand is XMM register:**

\[
\text{DEST}[63-0] \leftarrow \text{SRC}; \\
\text{DEST}[127-64] \leftarrow 0000000000000000H;
\]

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode
#PF(fault-code) For a page fault.
MOVSD—Move Scalar Double-Precision Floating-Point Value (Continued)

#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
MOVSS—Move Scalar Single-Precision Floating-Point Values

Description

Moves a scalar single-precision floating-point value from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be XMM registers or 32-bit memory locations. This instruction can be used to move a single-precision floating-point value to and from the low doubleword of an XMM register and a 32-bit memory location, or to move a single-precision floating-point value between the low doublewords of two XMM registers. The instruction cannot be used to transfer data between memory locations.

When the source and destination operands are XMM registers, the three high-order doublewords of the destination operand remain unchanged. When the source operand is a memory location and destination operand is an XMM registers, the three high-order doublewords of the destination operand are cleared to all 0s.

Operation

MOVSS instruction when source and destination operands are XMM registers:

\[ \text{DEST}[31-0] \leftarrow \text{SRC}[31-0]; \]
* \text{DEST}[127-32] remains unchanged *

MOVSS instruction when source operand is XMM register and destination operand is memory location:

\[ \text{DEST} \leftarrow \text{SRC}[31-0]; \]

MOVSS instruction when source operand is memory location and destination operand is XMM register:

\[ \text{DEST}[31-0] \leftarrow \text{SRC}; \]
\[ \text{DEST}[127-32] \leftarrow 000000000000000000000000H; \]

</tr>
<tr>
<td>66 0F 11 /r</td>
<td>MOVUPD xmm2/m128, xmm</td>
<td>Move packed double-precision floating-point values from xmm1 to xmm2/m128.</td>
</tr>
</tbody>
</table>

**Description**

Moves a double quadword containing two packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or move data between two XMM registers. When the source or destination operand is a memory operand, the operand may be unaligned on a 16-byte boundary without causing a general-protection exception (#GP) to be generated.

To move double-precision floating-point values to and from memory locations that are known to be aligned on 16-byte boundaries, use the MOVAPD instruction.

While executing in 16-bit addressing mode, a linear address for a 128-bit data access that overlaps the end of a 16-bit segment is not allowed and is defined as reserved behavior. A specific processor implementation may or may not generate a general-protection exception (#GP) in this situation, and the address that spans the end of the segment may or may not wrap around to the beginning of the segment.

**Operation**

\[ \text{DEST} \leftarrow \text{SRC}; \]  
* #GP if SRC or DEST unaligned memory operand *;

**Intel C/C++ Compiler Intrinsic Equivalent**

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode
#PF(fault-code) For a page fault.
MOVUPS—Move Unaligned Packed Single-Precision Floating-Point Values

**Description**

Moves a double quadword containing four packed single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or move data between two XMM registers. When the source or destination operand is a memory operand, the operand may be unaligned on a 16-byte boundary without causing a general-protection exception (#GP) to be generated.

To move packed single-precision floating-point values to and from memory locations that are known to be aligned on 16-byte boundaries, use the MOVAPS instruction.

While executing in 16-bit addressing mode, a linear address for a 128-bit data access that overlaps the end of a 16-bit segment is not allowed and is defined as reserved behavior. A specific processor implementation may or may not generate a general-protection exception (#GP) in this situation, and the address that spans the end of the segment may or may not wrap around to the beginning of the segment.

**Operation**

\[
\text{DEST} \leftarrow \text{SRC};
\]

* #GP if SRC or DEST unaligned memory operand *;

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.
MOVZX—Move with Zero-Extend (Continued)

#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
MUL—Unsigned Multiply

**Description**

Performs an unsigned multiplication of the first operand (destination operand) and the second operand (source operand) and stores the result in the destination operand. The destination operand is an implied operand located in register AL, AX or EAX (depending on the size of the operand); the source operand is located in a general-purpose register or a memory location. The action of this instruction and the location of the result depends on the opcode and the operand size as shown in the following table.

<table>
<thead>
<tr>
<th>Operand Size</th>
<th>Source 1</th>
<th>Source 2</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>AL</td>
<td>r/m8</td>
<td>AX</td>
</tr>
<tr>
<td>Word</td>
<td>AX</td>
<td>r/m16</td>
<td>DX:AX</td>
</tr>
<tr>
<td>Doubleword</td>
<td>EAX</td>
<td>r/m32</td>
<td>EDX:EAX</td>
</tr>
</tbody>
</table>

The result is stored in register AX, register pair DX:AX, or register pair EDX:EAX (depending on the operand size), with the high-order bits of the product contained in register AH, DX, or EDX, respectively. If the high-order bits of the product are 0, the CF and OF flags are cleared; otherwise, the flags are set.

**Operation**

IF byte operation

THEN

AX ← AL * SRC

ELSE (* word or doubleword operation *)

IF OperandSize ← 16

THEN

dx=ax * src

ELSE (* OperandSize ← 32 *)

EDX:EAX ← EAX * SRC

FI;

FI;

**Flags Affected**

The OF and CF flags are cleared to 0 if the upper half of the result is 0; otherwise, they are set to 1. The SF, ZF, AF, and PF flags are undefined.
MUL—Unsigned Multiply (Continued)

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
   If the DS, ES, FS, or GS register contains a null segment selector.

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 59/r</td>
<td>MULPS xmm1, xmm2/m128</td>
<td>Multiply packed single-precision floating-point values in xmm2/mem by xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Performs a SIMD multiply of the four packed single-precision floating-point values from the source operand (second operand) and the destination operand (first operand), and stores the packed single-precision floating-point results in the destination operand. The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 10-5 in the IA-32 Intel Architecture Software Developer’s Manual, Volume I for an illustration of a SIMD single-precision floating-point operation.

**Operation**

\[
\begin{align*}
\text{DEST}[31-0] & \leftarrow \text{DEST}[31-0] \times \text{SRC}[31-0]; \\

MULSD—Multiply Scalar Double-Precision Floating-Point Values

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2 0F 59 /r</td>
<td>MULSD xmm1, xmm2/m64</td>
<td>Multiply the low double-precision floating-point value in xmm2/mem64 by low double-precision floating-point value in xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Multiplies the low double-precision floating-point value in the source operand (second operand) by the low double-precision floating-point value in the destination operand (first operand), and stores the double-precision floating-point result in the destination operand. The source operand can be an XMM register or a 64-bit memory location. The destination operand is an XMM register. The high quadword of the destination operand remains unchanged. See Figure 11-4 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a scalar double-precision floating-point operation.

**Operation**

\[
\text{DEST}[63:0] \leftarrow \text{DEST}[63:0] \times \text{xmm2/m64}[63:0];
\]

* DEST[127:64] remains unchanged *

MULSS—Multiply Scalar Single-Precision Floating-Point Values

Description
Multiplies the low single-precision floating-point value from the source operand (second operand) by the low single-precision floating-point value in the destination operand (first operand), and stores the single-precision floating-point result in the destination operand. The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The three high-order doublewords of the destination operand remain unchanged. See Figure 10-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a scalar single-precision floating-point operation.

Operation
DEST[31-0] ← DEST[31-0] * SRC[31-0];
* DEST[127-32] remains unchanged *;

</tr>
<tr>
<td>F7 /3</td>
<td>NEG r/m32</td>
<td>Two’s complement negate r/m32</td>
</tr>
</tbody>
</table>

**Description**

Replaces the value of operand (the destination operand) with its two’s complement. (This operation is equivalent to subtracting the operand from 0.) The destination operand is located in a general-purpose register or a memory location.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

**Operation**

\[
\text{IF } \text{DEST} \leftarrow 0 \\
\quad \text{THEN } \text{CF} \leftarrow 0 \\
\quad \text{ELSE } \text{CF} \leftarrow 1; \\
\text{FI; } \\
\text{DEST} \leftarrow -\text{(DEST)}
\]

**Flags Affected**

The CF flag cleared to 0 if the source operand is 0; otherwise it is set to 1. The OF, SF, ZF, AF, and PF flags are set according to the result.

**Protected Mode Exceptions**

- #GP(0) If the destination is located in a nonwritable segment.
- #GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- #GP(0) If the DS, ES, FS, or GS register contains a null segment selector.
- #SS(0) If a memory operand effective address is outside the SS segment limit.
- #PF(fault-code) If a page fault occurs.
- #AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
NEG—Two’s Complement Negation (Continued)

Real-Address Mode Exceptions
#GP    If a memory operand effective address is outside the CS, DS, ES, FS, or
       GS segment limit.
#SS    If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or
       GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.

#AC(0) If alignment checking is enabled and an unaligned memory reference is
       made.
NOP—No Operation

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>90</td>
<td>NOP</td>
<td>No operation</td>
</tr>
</tbody>
</table>

**Description**
Performs no operation. This instruction is a one-byte instruction that takes up space in the instruction stream but does not affect the machine context, except the EIP register.

The NOP instruction is an alias mnemonic for the XCHG (E)AX, (E)AX instruction.

**Flags Affected**
None.

**Exceptions (All Operating Modes)**
None.
NOT—One’s Complement Negation

Description
Performs a bitwise NOT operation (each 1 is cleared to 0, and each 0 is set to 1) on the destination operand and stores the result in the destination operand location. The destination operand can be a register or a memory location.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation
DEST ← NOT DEST;

Flags Affected
None.

Protected Mode Exceptions
#GP(0) If the destination operand points to a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.
NOT—One's Complement Negation (Continued)

Virtual-8086 Mode Exceptions

#GP(0)  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0)  If a memory operand effective address is outside the SS segment limit.
#PF(fault-code)  If a page fault occurs.
#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.
OR—Logical Inclusive OR

Description
Performs a bitwise inclusive OR operation between the destination (first) and source (second) operands and stores the result in the destination operand location. The source operand can be an immediate, a register, or a memory location; the destination operand can be a register or a memory location. (However, two memory operands cannot be used in one instruction.) Each bit of the result of the OR instruction is set to 0 if both corresponding bits of the first and second operands are 0; otherwise, each bit is set to 1.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation
DEST ← DEST OR SRC;

Flags Affected
The OF and CF flags are cleared; the SF, ZF, and PF flags are set according to the result. The state of the AF flag is undefined.

Protected Mode Exceptions

#GP(0)  
If the destination operand points to a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.
OR—Logical Inclusive OR (Continued)

#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

<td>Output word in AX to I/O port address in DX</td>
</tr>
<tr>
<td>EF</td>
<td>OUT DX, EAX</td>
<td>Output doubleword in EAX to I/O port address in DX</td>
</tr>
</tbody>
</table>

Description

Copies the value from the second operand (source operand) to the I/O port specified with the destination operand (first operand). The source operand can be register AL, AX, or EAX, depending on the size of the port being accessed (8, 16, or 32 bits, respectively); the destination operand can be a byte-immediate or the DX register. Using a byte immediate allows I/O port addresses 0 to 255 to be accessed; using the DX register as a source operand allows I/O ports from 0 to 65,535 to be accessed.

The size of the I/O port being accessed is determined by the opcode for an 8-bit I/O port or by the operand-size attribute of the instruction for a 16- or 32-bit I/O port.

At the machine code level, I/O instructions are shorter when accessing 8-bit I/O ports. Here, the upper eight bits of the port address will be 0.

This instruction is only useful for accessing I/O ports located in the processor’s I/O address space. See Chapter 12, Input/Output, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for more information on accessing I/O ports in the I/O address space.

IA-32 Architecture Compatibility

After executing an OUT instruction, the Pentium processor insures that the EWBE# pin has been sampled active before it begins to execute the next instruction. (Note that the instruction can be prefetched if EWBE# is not active, but it will not be executed until the EWBE# pin is sampled active.) Only the Pentium processor family has the EWBE# pin; the other IA-32 processors do not.

Operation

IF ((PE ← 1) AND ((CPL > IOPL) OR (VM ← 1)))
    THEN (* Protected mode with CPL > IOPL or virtual-8086 mode *)
        IF (Any I/O Permission Bit for I/O port being accessed ← 1)
            THEN (* I/O operation is not allowed *)

        ELSE (* I/O operation is allowed *)
            DEST ← SRC; (* Writes to selected I/O port *)
    FI;
OUT—Output to Port (Continued)

ELSE (Real Mode or Protected Mode with CPL \leq IOPL *)
    DEST ← SRC; (* Writes to selected I/O port *)
FI;

Flags Affected
None.

Protected Mode Exceptions

#GP(0) If the CPL is greater than (has less privilege) the I/O privilege level (IOPL) and any of the corresponding I/O permission bits in TSS for the I/O port being accessed is 1.

Real-Address Mode Exceptions

None.

Virtual-8086 Mode Exceptions

#GP(0) If any of the I/O permission bits in the TSS for the I/O port being accessed is 1.
OUTS/OUTSB/OUTSW/OUTSD—Output String to Port

Description

Copies data from the source operand (second operand) to the I/O port specified with the destination operand (first operand). The source operand is a memory location, the address of which is read from either the DS:EDI or the DS:DI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). (The DS segment may be overridden with a segment override prefix.) The destination operand is an I/O port address (from 0 to 65,535) that is read from the DX register. The size of the I/O port being accessed (that is, the size of the source and destination operands) is determined by the opcode for an 8-bit I/O port or by the operand-size attribute of the instruction for a 16- or 32-bit I/O port.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the OUTS mnemonic) allows the source and destination operands to be specified explicitly. Here, the source operand should be a symbol that indicates the size of the I/O port and the source address, and the destination operand must be DX. This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the source operand symbol must specify the correct type (size) of the operand (byte, word, or doubleword), but it does not have to specify the correct location. The location is always specified by the DS:(E)SI registers, which must be loaded correctly before the OUTS instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the OUTS instructions. Here also DS:(E)SI is assumed to be the source operand and DX is assumed to be the destination operand. The size of the I/O port is specified with the choice of mnemonic: OUTSB (byte), OUTSW (word), or OUTSD (doubleword).

After the byte, word, or doubleword is transferred from the memory location to the I/O port, the (E)SI register is incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)SI register is incremented; if the DF flag is 1, the (E)SI register is decremented.) The (E)SI register is incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.

</tbody>
</table>
OUTS/OUTSB/OUTSW/OUTSD—Output String to Port (Continued)

The OUTS, OUTSB, OUTSW, and OUTSD instructions can be preceded by the REP prefix for block input of ECX bytes, words, or doublewords. See “REP/REPE/REPZ/REPNE /REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.

This instruction is only useful for accessing I/O ports located in the processor’s I/O address space. See Chapter 12, Input/Output, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for more information on accessing I/O ports in the I/O address space.

IA-32 Architecture Compatibility

After executing an OUTS, OUTSB, OUTSW, or OUTSD instruction, the Pentium processor insures that the EWBE# pin has been sampled active before it begins to execute the next instruction. (Note that the instruction can be prefetched if EWBE# is not active, but it will not be executed until the EWBE# pin is sampled active.) Only the Pentium processor family has the EWBE# pin; the other IA-32 processors do not. For the Pentium 4 and P6 family processors, upon execution of an OUTS, OUTSB, OUTSW, or OUTSD instruction, the processor will not execute the next instruction until the data phase of the transaction is complete.

</tbody>
</table>

### Description

Converts packed signed word integers into packed signed byte integers (PACKSSWB) or converts packed signed doubleword integers into packed signed word integers (PACKSSDW), using saturation to handle overflow conditions. See Figure 3-5 for an example of the packing operation.

![Figure 3-5. Operation of the PACKSSDW Instruction Using 64-bit Operands.](image)

The PACKSSWB instruction converts 4 or 8 signed word integers from the destination operand (first operand) and 4 or 8 signed word integers from the source operand (second operand) into 8 or 16 signed byte integers and stores the result in the destination operand. If a signed word integer value is beyond the range of a signed byte integer (that is, greater than 7FH for a positive integer or greater than 80H for a negative integer), the saturated signed byte integer value of 7FH or 80H, respectively, is stored in the destination.
PACKSSWB/PACKSSDW—Pack with Signed Saturation  
(Continued)

The PACKSSDW instruction packs 2 or 4 signed doublewords from the destination operand  
(first operand) and 2 or 4 signed doublewords from the source operand (second operand) into 4  
or 8 signed words in the destination operand (see Figure 3-5). If a signed doubleword integer  
value is beyond the range of a signed word (that is, greater than 7FFFH for a positive integer or  
greater than 8000H for a negative integer), the saturated signed word integer value of 7FFFH or  
8000H, respectively, is stored into the destination.

The PACKSSWB and PACKSSDW instructions operate on either 64-bit or 128-bit operands.  
When operating on 64-bit operands, the destination operand must be an MMX register and the  
source operand can be either an MMX register or a 64-bit memory location. When operating on  
128-bit operands, the destination operand must be an XMM register and the source operand can  
be either an XMM register or a 128-bit memory location.

Operation

PACKSSWB instruction with 64-bit operands

DEST[7..0] ← SaturateSignedWordToSignedByte DEST[15..0];
DEST[15..8] ← SaturateSignedWordToSignedByte DEST[31..16];
DEST[23..16] ← SaturateSignedWordToSignedByte DEST[47..32];

PACKUSWB—Pack with Unsigned Saturation

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 67 /r</td>
<td>PACKUSWB mm, mm/m64</td>
<td>Converts 4 signed word integers from mm and 4 signed word integers from mm/m64 into 8 unsigned byte integers in mm using unsigned saturation.</td>
</tr>
<tr>
<td>66 0F 67 /r</td>
<td>PACKUSWB xmm1, xmm2/m128</td>
<td>Converts 8 signed word integers from xmm1 and 8 signed word integers from xmm2/m128 into 16 unsigned byte integers in xmm1 using unsigned saturation.</td>
</tr>
</tbody>
</table>

**Description**

Converts 4 or 8 signed word integers from the destination operand (first operand) and 4 or 8 signed word integers from the source operand (second operand) into 8 or 16 unsigned byte integers and stores the result in the destination operand. (See Figure 3-5 for an example of the packing operation.) If a signed word integer value is beyond the range of an unsigned byte integer (that is, greater than FFH or less than 00H), the saturated unsigned byte integer value of FFH or 00H, respectively, is stored in the destination.

The PACKUSWB instruction operates on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

**Operation**

**PACKUSWB instruction with 64-bit operands:**

\[
\begin{align*}
\text{DEST}[7\ldots0] & \leftarrow \text{SaturateSignedWordToUnsignedByte} \ \text{DEST}[15\ldots0]; \\
\text{DEST}[15\ldots8] & \leftarrow \text{SaturateSignedWordToUnsignedByte} \ \text{DEST}[31\ldots16]; \\
\text{DEST}[23\ldots16] & \leftarrow \text{SaturateSignedWordToUnsignedByte} \ \text{DEST}[47\ldots32]; \\
\text{DEST}[31\ldots24] & \leftarrow \text{SaturateSignedWordToUnsignedByte} \ \text{DEST}[63\ldots48]; \\
\text{DEST}[39\ldots32] & \leftarrow \text{SaturateSignedWordToUnsignedByte} \ \text{SRC}[15\ldots0]; \\

</tr>
</tbody>
</table>

Description

Performs a SIMD add of the packed integers from the source operand (second operand) and the destination operand (first operand), and stores the packed integer results in the destination operand. See Figure 9-4 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a SIMD operation. Overflow is handled with wraparound, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PADDB instruction adds packed byte integers. When an individual result is too large to be represented in 8 bits (overflow), the result is wrapped around and the low 8 bits are written to the destination operand (that is, the carry is ignored).

The PADDW instruction adds packed word integers. When an individual result is too large to be represented in 16 bits (overflow), the result is wrapped around and the low 16 bits are written to the destination operand.

The PADDD instruction adds packed doubleword integers. When an individual result is too large to be represented in 32 bits (overflow), the result is wrapped around and the low 32 bits are written to the destination operand.

Note that the PADDB, PADDW, and PADDD instructions can operate on either unsigned or signed (two's complement notation) packed integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of values operated on.
PADDB/PADDW/PADDD—Add Packed Integers (Continued)

Operation

PADDB instruction with 64-bit operands:
DEST[7..0] ← DEST[7..0] + SRC[7..0];
* repeat add operation for 2nd through 7th byte *;
DEST[63..56] ← DEST[63..56] + SRC[63..56];

PADDB instruction with 128-bit operands:
DEST[7-0] ← DEST[7-0] + SRC[7-0];
* repeat add operation for 2nd through 14th byte *;
DEST[127-120] ← DEST[111-120] + SRC[127-120];

PADDW instruction with 64-bit operands:
DEST[15..0] ← DEST[15..0] + SRC[15..0];
* repeat add operation for 2nd and 3th word *;
DEST[63..48] ← DEST[63..48] + SRC[63..48];

PADDW instruction with 128-bit operands:
DEST[15-0] ← DEST[15-0] + SRC[15-0];
* repeat add operation for 2nd through 7th word *;

PADDD instruction with 64-bit operands:
DEST[31..0] ← DEST[31..0] + SRC[31..0];
DEST[63..32] ← DEST[63..32] + SRC[63..32];

PADDD instruction with 128-bit operands:
DEST[31-0] ← DEST[31-0] + SRC[31-0];
* repeat add operation for 2nd and 3th doubleword *;

INSTRUCTION SET REFERENCE

PADDQ—Add Packed Quadword Integers

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F D4 /r</td>
<td>PADDQ mm1,mm2/m64</td>
<td>Add quadword integer mm2/m64 to mm1</td>
</tr>
<tr>
<td>66 0F D4 /r</td>
<td>PADDQ xmm1,xmm2/m128</td>
<td>Add packed quadword integers xmm2/m128 to xmm1</td>
</tr>
</tbody>
</table>

Description

Adds the first operand (destination operand) to the second operand (source operand) and stores the result in the destination operand. The source operand can be a quadword integer stored in an MMX register or a 64-bit memory location, or it can be two packed quadword integers stored in an XMM register or an 128-bit memory location. The destination operand can be a quadword integer stored in an MMX register or two packed quadword integers stored in an XMM register. When packed quadword operands are used, a SIMD add is performed. When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

Note that the PADDQ instruction can operate on either unsigned or signed (two’s complement notation) integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of the values operated on.

Operation

PADDQ instruction with 64-Bit operands:

DEST[63-0] := DEST[63-0] + SRC[63-0];

PADDQ instruction with 128-Bit operands:

DEST[63-0] := DEST[63-0] + SRC[63-0];

DEST[127-64] := DEST[127-64] + SRC[127-64];

Description

Performs a SIMD add of the packed signed integers from the source operand (second operand) and the destination operand (first operand), and stores the packed integer results in the destination operand. See Figure 9-4 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a SIMD operation. Overflow is handled with signed saturation, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PADDSB instruction adds packed signed byte integers. When an individual byte result is beyond the range of a signed byte integer (that is, greater than 7FH or less than 80H), the saturated value of 7FH or 80H, respectively, is written to the destination operand.

The PADDSW instruction adds packed signed word integers. When an individual word result is beyond the range of a signed word integer (that is, greater than 7FFFH or less than 8000H), the saturated value of 7FFFH or 8000H, respectively, is written to the destination operand.

Operation

PADDSB instruction with 64-bit operands:

\[
\text{DEST}[7..0] \leftarrow \text{SaturateToSignedByte} (\text{DEST}[7..0] + \text{SRC}[7..0]) ;
\]

* repeat add operation for 2nd through 7th bytes *

\[
\text{DEST}[63..56] \leftarrow \text{SaturateToSignedByte} (\text{DEST}[63..56] + \text{SRC}[63..56]) ;
\]

PADDSB instruction with 128-bit operands:

\[
\text{DEST}[7-0] \leftarrow \text{SaturateToSignedByte} (\text{DEST}[7-0] + \text{SRC}[7-0]);
\]

* repeat add operation for 2nd through 14th bytes *

\[
\text{DEST}[127-120] \leftarrow \text{SaturateToSignedByte} (\text{DEST}[111-120] + \text{SRC}[127-120]);
\]
PADDSB/PADDSW—Add Packed Signed Integers with Signed Saturation (Continued)

PADDSW instruction with 64-bit operands
   DEST[15..0] ← SaturateToSignedWord(Destination[15..0] + Source[15..0]);
   * repeat add operation for 2nd and 7th words *
   DEST[63..48] ← SaturateToSignedWord(Destination[63..48] + Source[63..48]);

PADDSW instruction with 128-bit operands
   DEST[15-0] ← SaturateToSignedWord(Destination[15-0] + Source[15-0]);
   * repeat add operation for 2nd through 7th words *

<td>Add packed unsigned word integers from xmm2/m128 to xmm1 and saturate the results.</td>
</tr>
</tbody>
</table>

Description

Performs a SIMD add of the packed unsigned integers from the source operand (second operand) and the destination operand (first operand), and stores the packed integer results in the destination operand. See Figure 9-4 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1 for an illustration of a SIMD operation. Overflow is handled with unsigned saturation, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PADDUSB instruction adds packed unsigned byte integers. When an individual byte result is beyond the range of an unsigned byte integer (that is, greater than FFH), the saturated value of FFH is written to the destination operand.

The PADDUSW instruction adds packed unsigned word integers. When an individual word result is beyond the range of an unsigned word integer (that is, greater than FFFFH), the saturated value of FFFFH is written to the destination operand.

Operation

PADDUSB instruction with 64-bit operands:

\[
\text{DEST}[7..0] \leftarrow \text{SaturateToUnsignedByte(DEST}[7..0] + \text{SRC}[7..0])
\]

* repeat add operation for 2nd through 7th bytes *:

\[
\text{DEST}[63..56] \leftarrow \text{SaturateToUnsignedByte(DEST}[63..56] + \text{SRC}[63..56])
\]

PADDUSB instruction with 128-bit operands:

\[
\text{DEST}[7..0] \leftarrow \text{SaturateToUnsignedByte}(\text{DEST}[7..0] + \text{SRC}[7..0])
\]

* repeat add operation for 2nd through 14th bytes *:

\[
\text{DEST}[127..120] \leftarrow \text{SaturateToUnsignedByte}(\text{DEST}[127..120] + \text{SRC}[127..120])
\]
PADDUSB/PADDUSW—Add Packed Unsigned Integers with Unsigned Saturation (Continued)

<td>Bitwise AND of xmm2/m128 and xmm1.</td>
</tr>
</tbody>
</table>

Description

Performs a bitwise logical AND operation on the source operand (second operand) and the destination operand (first operand) and stores the result in the destination operand. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register. Each bit of the result is set to 1 if the corresponding bits of the first and second operands are 1; otherwise, it is set to 0.

Operation

DEST ← DEST AND SRC;

PANDN—Logical AND NOT

**Description**

Performs a bitwise logical NOT of the destination operand (first operand), then performs a bitwise logical AND of the source operand (second operand) and the inverted destination operand. The result is stored in the destination operand. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register. Each bit of the result is set to 1 if the corresponding bit in the first operand is 0 and the corresponding bit in the second operand is 1; otherwise, it is set to 0.

**Operation**

DEST ← (NOT DEST) AND SRC;

PAUSE—Spin Loop Hint

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F3 90</td>
<td>PAUSE</td>
<td>Gives hint to processor that improves performance of spin-wait loops.</td>
</tr>
</tbody>
</table>

Description

Improves the performance of spin-wait loops. When executing a “spin-wait loop,” a Pentium 4 processor suffers a severe performance penalty when exiting the loop because it detects a possible memory order violation. The PAUSE instruction provides a hint to the processor that the code sequence is a spin-wait loop. The processor uses this hint to bypass the memory order violation in most situations, which greatly improves processor performance. For this reason, it is recommended that a PAUSE instruction be placed in all spin-wait loops.

An additional function of the PAUSE instruction is to reduce the power consumed by a Pentium 4 processor while executing a spin loop. The Pentium 4 processor can execute a spin-wait loop extremely quickly, causing the processor to consume a lot of power while it waits for the resource it is spinning on to become available. Inserting a pause instruction in a spin-wait loop greatly reduces the processor’s power consumption.

This instruction was introduced in the Pentium 4 processors, but is backward compatible with all IA-32 processors. In earlier IA-32 processors, the PAUSE instruction operates like a NOP instruction.

The Pentium 4 processor implements the PAUSE instruction as a pre-defined delay. The delay is finite and can be zero for some processors. This instruction does not change the architectural state of the processor (that is, it performs essentially a delaying no-op operation).

Operation

Execute_Next_Instruction(DELAY);

PAVGB/PAVGW—Average Packed Integers

Description
Performs a SIMD average of the packed unsigned integers from the source operand (second operand) and the destination operand (first operand), and stores the results in the destination operand. For each corresponding pair of data elements in the first and second operands, the elements are added together, a 1 is added to the temporary sum, and that result is shifted right one bit position. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register.

The PAVGB instruction operates on packed unsigned bytes and the PAVGW instruction operates on packed unsigned words.

Operation
PAVGB instruction with 64-bit operands:
\[
\text{SRC}(7-0) \leftarrow (\text{SRC}(7-0) + \text{DEST}(7-0) + 1) >> 1; \quad \text{* temp sum before shifting is 9 bits *}
\]
* repeat operation performed for bytes 2 through 6;
\[
\text{SRC}(63-56) \leftarrow (\text{SRC}(63-56) + \text{DEST}(63-56) + 1) >> 1;
\]

PAVGB instruction with 128-bit operands:
\[
\text{SRC}(7-0) \leftarrow (\text{SRC}(7-0) + \text{DEST}(7-0) + 1) >> 1; \quad \text{* temp sum before shifting is 9 bits *}
\]
* repeat operation performed for bytes 2 through 14;
\[
\text{SRC}(63-56) \leftarrow (\text{SRC}(63-56) + \text{DEST}(63-56) + 1) >> 1;
\]

PAVGW instruction with 64-bit operands:
\[
\text{SRC}(15-0) \leftarrow (\text{SRC}(15-0) + \text{DEST}(15-0) + 1) >> 1; \quad \text{* temp sum before shifting is 17 bits *}
\]
* repeat operation performed for words 2 and 3;
\[
\text{SRC}(64-48) \leftarrow (\text{SRC}(64-48) + \text{DEST}(64-48) + 1) >> 1;
\]

PAVGW instruction with 128-bit operands:
\[
\text{SRC}(15-0) \leftarrow (\text{SRC}(15-0) + \text{DEST}(15-0) + 1) >> 1; \quad \text{* temp sum before shifting is 17 bits *}
\]
* repeat operation performed for words 2 through 6;
\[
\text{SRC}(127-48) \leftarrow (\text{SRC}(127-112) + \text{DEST}(127-112) + 1) >> 1;

<td>PCMPEQD xmm1, xmm2/m128</td>
<td>Compare packed doublewords in xmm2/m128 and xmm1 for equality.</td>
</tr>
</tbody>
</table>

Description

Performs a SIMD compare for equality of the packed bytes, words, or doublewords in the destination operand (first operand) and the source operand (second operand). If a pair of data elements is equal, the corresponding data element in the destination operand is set to all 1s; otherwise, it is set to all 0s. The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register.

The PCMPEQB instruction compares the corresponding bytes in the destination and source operands; the PCMPEQW instruction compares the corresponding words in the destination and source operands; and the PCMPEQD instruction compares the corresponding doublewords in the destination and source operands.

Operation

PCMPEQB instruction with 64-bit operands:

IF DEST[7..0] = SRC[7..0]
THEN DEST[7 0] ← FFH;
ELSE DEST[7..0] ← 0;

* Continue comparison of 2nd through 7th bytes in DEST and SRC *

IF DEST[63..56] = SRC[63..56]
THEN DEST[63..56] ← FFH;
ELSE DEST[63..56] ← 0;

PCMPEQB instruction with 128-bit operands:

IF DEST[7..0] = SRC[7..0]
THEN DEST[7 0] ← FFH;
ELSE DEST[7..0] ← 0;
PCMPEQB/PCMPEQW/PCMPEQD—Compare Packed Data for Equal (Continued)

* Continue comparison of 2nd through 15th bytes in DEST and SRC *
IF DEST[63..56] = SRC[63..56]
  THEN DEST[63..56] ← FFH;
  ELSE DEST[63..56] ← 0;

PCMPEQW instruction with 64-bit operands:
IF DEST[15..0] = SRC[15..0]
  THEN DEST[15..0] ← FFFFH;
  ELSE DEST[15..0] ← 0;

* Continue comparison of 2nd and 3rd words in DEST and SRC *

INSTRUCTION SET REFERENCE

PCMPGTB/PCMPGTW/PCMPGTD—Compare Packed Signed Integers for Greater Than

Description
Performs a SIMD signed compare for the greater value of the packed byte, word, or doubleword integers in the destination operand (first operand) and the source operand (second operand). If a data element in the destination operand is greater than the corresponding data element in the source operand, the corresponding data element in the destination operand is set to all 1s; otherwise, it is set to all 0s. The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register.

The PCMPGTB instruction compares the corresponding signed byte integers in the destination and source operands; the PCMPGTW instruction compares the corresponding signed word integers in the destination and source operands; and the PCMPGTD instruction compares the corresponding signed doubleword integers in the destination and source operands.

Operation
PCMPGTB instruction with 64-bit operands:
IF DEST[7..0] > SRC[7..0]
    THEN DEST[7..0] ← FFH;
ELSE DEST[7..0] ← 0;
* Continue comparison of 2nd through 7th bytes in DEST and SRC *
IF DEST[63..56] > SRC[63..56]
    THEN DEST[63..56] ← FFH;
ELSE DEST[63..56] ← 0;

PEXTRW—Extract Word

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F C5 /r ib</td>
<td>PEXTRW r32, mm, imm8</td>
<td>Extract the word specified by imm8 from mm and move it to r32.</td>
</tr>
<tr>
<td>66 0F C5 /r ib</td>
<td>PEXTRW r32, xmm, imm8</td>
<td>Extract the word specified by imm8 from xmm and move it to a r32.</td>
</tr>
</tbody>
</table>

Description

Copies the word in the source operand (second operand) specified by the count operand (third operand) to the destination operand (first operand). The source operand can be an MMX or an XMM register. The destination operand is the low word of a general-purpose register. The count operand is an 8-bit immediate. When specifying a word location in an MMX register, the 2 least-significant bits of the count operand specify the location; for an XMM register, the 4 least-significant bits specify the location. The high word of the destination operand is cleared (set to all 0s).

Operation

PEXTRW instruction with 64-bit source operand:

SEL ← COUNT AND 3H;
TEMP ← (SRC >> (SEL * 16)) AND FFFFH;
r32[15-0] ← TEMP[15-0];
r32[31-16] ← 0000H;

PEXTRW instruction with 128-bit source operand:

SEL ← COUNT AND 7H;
TEMP ← (SRC >> (SEL * 16)) AND FFFFH;
r32[15-0] ← TEMP[15-0];
r32[31-16] ← 0000H;

#PF(fault-code) If a page fault occurs.

#AC(0) (64-bit operations only.) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP(0) (128-bit operations only.) If memory operand is not aligned on a 16-byte boundary, regardless of segment.

If any part of the operand lies outside of the effective address space from 0 to FFFFH.

#UD If EM in CR0 is set.

(128-bit operations only.) If OSFXSR in CR4 is 0.

(128-bit operations only.) If CPUID feature flag SSE2 is 0.

#NM If TS in CR0 is set.

#MF (64-bit operations only.) If there is a pending x87 FPU exception.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) (64-bit operations only.) If alignment checking is enabled and an unaligned memory reference is made.

Numeric Exceptions

None.
PINSRW—Insert Word

**Description**
Copies a word from the source operand (second operand) and inserts it in the destination operand (first operand) at the location specified with the count operand (third operand). (The other words in the destination register are left untouched.) The source operand can be a general-purpose register or a 16-bit memory location. (When the source operand is a general-purpose register, the low word of the register is copied.) The destination operand can be an MMX register or an XMM register. The count operand is an 8-bit immediate. When specifying a word location in an MMX register, the 2 least-significant bits of the count operand specify the location; for an XMM register, the 4 least-significant bits specify the location.

**Operation**
PINSRW instruction with 64-bit source operand:

Sel ← COUNT AND 3H;
CASE (determine word position) OF
  Sel ← 0: MASK ← 000000000000FFFFH;
  Sel ← 1: MASK ← 00000000FFFF0000H;
  Sel ← 2: MASK ← 0000FFFF00000000H;
  Sel ← 3: MASK ← FFFF000000000000H;
DEST ← (DEST AND NOT MASK) OR (((SRC << (Sel * 16)) AND MASK);

PINSRW instruction with 128-bit source operand:

Sel ← COUNT AND 7H;
CASE (determine word position) OF
  Sel ← 0: MASK ← 0000000000000000FFFFFFFFH;
  Sel ← 1: MASK ← 0000000000000000FFFFFFFF0000H;
  Sel ← 2: MASK ← 0000000000000000FFFF00000000H;
  Sel ← 3: MASK ← 0000000000000000FFFF000000000000H;
  Sel ← 4: MASK ← 0000000000000000FFFF000000000000000H;
  Sel ← 5: MASK ← 0000000000000000FFFF0000000000000000000H;
  Sel ← 6: MASK ← 0000000000000000FFFF00000000000000000000000H;
  Sel ← 7: MASK ← FFFF00000000000000000000000000000000000000H;
DEST ← (DEST AND NOT MASK) OR (((SRC << (Sel * 16)) AND MASK);

PMADDWD—Multiply and Add Packed Integers

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F F5 /r</td>
<td>PMADDWD mm, mm/m64</td>
<td>Multiply the packed words in mm by the packed words in mm/m64, add adjacent doubleword results, and store in mm.</td>
</tr>
<tr>
<td>66 0F F5 /r</td>
<td>PMADDWD xmm1, xmm2/m128</td>
<td>Multiply the packed word integers in xmm1 by the packed word integers in xmm2/m128, add adjacent doubleword results, and store in xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Multiplies the individual signed words of the destination operand (first operand) by the corresponding signed words of the source operand (second operand), producing temporary signed, doubleword results. The adjacent doubleword results are then summed and stored in the destination operand. For example, the corresponding low-order words (15-0) and (31-16) in the source and destination operands are multiplied by one another and the doubleword results are added together and stored in the low doubleword of the destination register (31-0). The same operation is performed on the other pairs of adjacent words. (Figure 3-6 shows this operation when using 64-bit operands.) The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register.

The PMADDWD instruction wraps around only in one situation: when the 2 pairs of words being operated on in a group are all 8000H. In this case, the result wraps around to 80000000H.

![Figure 3-6. PMADDWD Execution Model Using 64-bit Operands](image)

**Operation**

PMADDWD instruction with 64-bit operands:

\[
\begin{align*}
\text{DEST}[31..0] & \leftarrow (\text{DEST}[15..0] \times \text{SRC}[15..0]) + (\text{DEST}[31..16] \times \text{SRC}[31..16]); \\

<td>PMAXSW xmm1, xmm2/m128</td>
<td>Compare signed word integers in xmm2/m128 and xmm1 and return maximum values.</td>
</tr>
</tbody>
</table>

Description

Performs a SIMD compare of the packed signed word integers in the destination operand (first operand) and the source operand (second operand), and returns the maximum value for each pair of word integers to the destination operand. The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register.

Operation

PMAXSW instruction for 64-bit operands:

IF DEST[15-0] > SRC[15-0]) THEN
    (DEST[15-0] ← DEST[15-0];
ELSE
    (DEST[15-0] ← SRC[15-0];
FI

* repeat operation for 2nd and 3rd words in source and destination operands *

IF DEST[63-48] > SRC[63-48]) THEN
    (DEST[63-48] ← DEST[63-48];
ELSE
    (DEST[63-48] ← SRC[63-48];
FI

PMAXSW instruction for 128-bit operands:

IF DEST[15-0] > SRC[15-0]) THEN
    (DEST[15-0] ← DEST[15-0];
ELSE
    (DEST[15-0] ← SRC[15-0];
FI

* repeat operation for 2nd through 7th words in source and destination operands *

IF DEST[127-112] > SRC[127-112]) THEN
    (DEST[127-112] ← DEST[127-112];
ELSE
    (DEST[127-112] ← SRC[127-112];

PMOVMSKB—Move Byte Mask

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F D7</td>
<td>PMOVMSKB r32, mm</td>
<td>Move a byte mask of mm to r32.</td>
</tr>
<tr>
<td>66 0F D7</td>
<td>PMOVMSKB r32, xmm</td>
<td>Move a byte mask of xmm to r32.</td>
</tr>
</tbody>
</table>

Description

Creates a mask made up of the most significant bit of each byte of the source operand (second operand) and stores the result in the low byte or word of the destination operand (first operand). The source operand is an MMX or an XMM register; the destination operand is a general-purpose register. When operating on 64-bit operands, the byte mask is 8 bits; when operating on 128-bit operands, the byte mask is 16-bits.

Operation

PMOVMSKB instruction with 64-bit source operand:
\[ r32[0] \leftarrow \text{SRC}[7]; \]
\[ r32[1] \leftarrow \text{SRC}[15]; \]
* repeat operation for bytes 2 through 6;
\[ r32[7] \leftarrow \text{SRC}[63]; \]
\[ r32[31-8] \leftarrow \text{000000H}; \]

PMOVMSKB instruction with 128-bit source operand:
\[ r32[0] \leftarrow \text{SRC}[7]; \]
\[ r32[1] \leftarrow \text{SRC}[15]; \]
* repeat operation for bytes 2 through 14;
\[ r32[15] \leftarrow \text{SRC}[127]; \]
\[ r32[31-16] \leftarrow \text{0000H}; \]

PMULHUW—Multiply Packed Unsigned Integers and Store High Result

**Description**

Performs a SIMD unsigned multiply of the packed unsigned word integers in the destination operand (first operand) and the source operand (second operand), and stores the high 16 bits of each 32-bit intermediate results in the destination operand. (Figure 3-7 shows this operation when using 64-bit operands.) The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register.

**Operation**

PMULHUW instruction with 64-bit operands:

```plaintext
TEMP0[31-0] ← DEST[15-0] * SRC[15-0]; * Unsigned multiplication *
TEMP1[31-0] ← DEST[31-16] * SRC[31-16];
TEMP2[31-0] ← DEST[47-32] * SRC[47-32];

Same exceptions as in Real Address Mode

#PF(fault-code)  For a page fault.

#AC(0)  (64-bit operations only.) If alignment checking is enabled and an unaligned memory reference is made.

Numeric Exceptions

None.
PMULUDQ—Multiply Packed Unsigned Doubleword Integers

Description

Multiplies the first operand (destination operand) by the second operand (source operand) and stores the result in the destination operand. The source operand can be a unsigned doubleword integer stored in the low doubleword of an MMX register or a 64-bit memory location, or it can be two packed unsigned doubleword integers stored in the first (low) and third doublewords of an XMM register or an 128-bit memory location. The destination operand can be a unsigned doubleword integer stored in the low doubleword an MMX register or two packed doubleword integers stored in the first and third doublewords of an XMM register. The result is an unsigned quadword integer stored in the destination an MMX register or two packed unsigned quadword integers stored in an XMM register. When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

For 64-bit memory operands, 64 bits are fetched from memory, but only the low doubleword is used in the computation; for 128-bit memory operands, 128 bits are fetched from memory, but only the first and third doublewords are used in the computation.

Operation

PMULUDQ instruction with 64-Bit operands:
DEST[63-0] ← DEST[31-0] * SRC[31-0];

PMULUDQ instruction with 128-Bit operands:
DEST[63-0] ← DEST[31-0] * SRC[31-0];
DEST[127-64] ← DEST[95-64] * SRC[95-64];

POP—Pop a Value from the Stack

Description

Loads the value from the top of the stack to the location specified with the destination operand and then increments the stack pointer. The destination operand can be a general-purpose register, memory location, or segment register.

The address-size attribute of the stack segment determines the stack pointer size (16 bits or 32 bits—the source address size), and the operand-size attribute of the current code segment determines the amount the stack pointer is incremented (2 bytes or 4 bytes). For example, if these address- and operand-size attributes are 32, the 32-bit ESP register (stack pointer) is incremented by 4 and, if they are 16, the 16-bit SP register is incremented by 2. (The B flag in the stack segment’s segment descriptor determines the stack’s address-size attribute, and the D flag in the current code segment’s segment descriptor, along with prefixes, determines the operand-size attribute and also the address-size attribute of the destination operand.)

If the destination operand is one of the segment registers DS, ES, FS, GS, or SS, the value loaded into the register must be a valid segment selector. In protected mode, popping a segment selector into a segment register automatically causes the descriptor information associated with that segment selector to be loaded into the hidden (shadow) part of the segment register and causes the selector and the descriptor information to be validated (see the “Operation” section below).

A null value (0000-0003) may be popped into the DS, ES, FS, or GS register without causing a general protection fault. However, any subsequent attempt to reference a segment whose corresponding segment register is loaded with a null value causes a general protection exception (#GP). In this situation, no memory reference occurs and the saved value of the segment register is null.

The POP instruction cannot pop a value into the CS register. To load the CS register from the stack, use the RET instruction.

If the ESP register is used as a base register for addressing a destination operand in memory, the POP instruction computes the effective address of the operand after it increments the ESP register. For the case of a 16-bit stack where ESP wraps to 0h as a result of the POP instruction, the resulting location of the memory write is processor-family-specific.

</tbody>
</table>
POP—Pop a Value from the Stack (Continued)

The POP ESP instruction increments the stack pointer (ESP) before data at the old top of stack is written into the destination.

A POP SS instruction inhibits all interrupts, including the NMI interrupt, until after execution of the next instruction. This action allows sequential execution of POP SS and MOV ESP, EBP instructions without the danger of having an invalid stack during an interrupt. However, use of the LSS instruction is the preferred method of loading the SS and ESP registers.

Operation

IF StackAddrSize ← 32
THEN
  IF OperandSize ← 32
  THEN
    DEST ← SS:ESP; (* copy a doubleword *)
    ESP ← ESP + 4;
  ELSE (* OperandSize ← 16*)

  THEN
    DEST ← SS:SP; (* copy a word *)
    SP ← SP + 2;
  ELSE (* OperandSize ← 32 *)
    DEST ← SS:SP; (* copy a doubleword *)
    SP ← SP + 4;
  FI;
FI;

Loading a segment register while in protected mode results in special checks and actions, as described in the following listing. These checks are performed on the segment selector and the segment descriptor it points to.

IF SS is loaded;
THEN
  IF segment selector is null
  THEN #GP(0);

1. Note that in a sequence of instructions that individually delay interrupts past the following instruction, only the first instruction in the sequence is guaranteed to delay the interrupt, but subsequent interrupt-delaying instructions may not delay the interrupt. Thus, in the following instruction sequence:

   STI
   POP SS
   POP ESP

   interrupts may be recognized before the POP ESP executes, because STI also delays interrupts for one instruction.
POP—Pop a Value from the Stack (Continued)

FI;
IF segment selector index is outside descriptor table limits
  OR segment selector’s RPL ≠ CPL
  OR segment is not a writable data segment
  OR DPL ≠ CPL
    THEN #GP(selector);

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If an unaligned memory reference is made while alignment checking is enabled.
POPA/POPAD—Pop All General-Purpose Registers

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>61</td>
<td>POPA</td>
<td>Pop DI, SI, BP, BX, DX, CX, and AX</td>
</tr>
<tr>
<td>61</td>
<td>POPAD</td>
<td>Pop EDI, ESI, EBP, EBX, EDX, ECX, and EAX</td>
</tr>
</tbody>
</table>

**Description**

Pops doublewords (POPAD) or words (POPA) from the stack into the general-purpose registers. The registers are loaded in the following order: EDI, ESI, EBP, EBX, EDX, ECX, and EAX (if the operand-size attribute is 32) and DI, SI, BP, BX, DX, CX, and AX (if the operand-size attribute is 16). (These instructions reverse the operation of the PUSHA/PUSHAD instructions.) The value on the stack for the ESP or SP register is ignored. Instead, the ESP or SP register is incremented after each register is loaded.

The POPA (pop all) and POPAD (pop all double) mnemonics reference the same opcode. The POPA instruction is intended for use when the operand-size attribute is 16 and the POPAD instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when POPA is used and to 32 when POPAD is used (using the operand-size override prefix [66H] if necessary). Others may treat these mnemonics as synonyms (POPA/POPAD) and use the current setting of the operand-size attribute to determine the size of values to be popped from the stack, regardless of the mnemonic used. (The D flag in the current code segment’s segment descriptor determines the operand-size attribute.)

**Operation**

IF OperandSize ← 32 (* instruction ← POPAD *)

THEN

- EDI ← Pop();
- ESI ← Pop();
- EBP ← Pop();
- increment ESP by 4 (* skip next 4 bytes of stack *)
- EBX ← Pop();
- EDX ← Pop();
- ECX ← Pop();
- EAX ← Pop();

ELSE (* OperandSize ← 16, instruction ← POPA *)

- DI ← Pop();
- SI ← Pop();
- BP ← Pop();
- increment ESP by 2 (* skip next 2 bytes of stack *)
- BX ← Pop();
- DX ← Pop();
- CX ← Pop();
- AX ← Pop();

FI;

is 3 and alignment checking is enabled.

Real-Address Mode Exceptions
#SS If the starting or ending stack address is not within the stack segment.

Virtual-8086 Mode Exceptions
#SS(0) If the starting or ending stack address is not within the stack segment.
#PF(fault-code) If a page fault occurs.
#AC(0) If an unaligned memory reference is made while alignment checking is
enabled.
POPF/POPFD—Pop Stack into EFLAGS Register

**Description**

Pops a doubleword (POPFD) from the top of the stack (if the current operand-size attribute is 32) and stores the value in the EFLAGS register, or pops a word from the top of the stack (if the operand-size attribute is 16) and stores it in the lower 16 bits of the EFLAGS register (that is, the FLAGS register). These instructions reverse the operation of the PUSHF/PUSHFD instructions.

The POPF (pop flags) and POPFD (pop flags double) mnemonics reference the same opcode. The POPF instruction is intended for use when the operand-size attribute is 16 and the POPFD instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when POPF is used and to 32 when POPFD is used. Others may treat these mnemonics as synonyms (POPF/POPFD) and use the current setting of the operand-size attribute to determine the size of values to be popped from the stack, regardless of the mnemonic used.

The effect of the POPF/POPFD instructions on the EFLAGS register changes slightly, depending on the mode of operation of the processor. When the processor is operating in protected mode at privilege level 0 (or in real-address mode, which is equivalent to privilege level 0), all the non-reserved flags in the EFLAGS register except the VIP, VIF, and VM flags can be modified. The VIP and VIF flags are cleared, and the VM flag is unaffected.

When operating in protected mode, with a privilege level greater than 0, but less than or equal to IOPL, all the flags can be modified except the IOPL field and the VIP, VIF, and VM flags. Here, the IOPL flags are unaffected, the VIP and VIF flags are cleared, and the VM flag is unaffected. The interrupt flag (IF) is altered only when executing at a level at least as privileged as the IOPL. If a POPF/POPFD instruction is executed with insufficient privilege, an exception does not occur, but the privileged bits do not change.

When operating in virtual-8086 mode, the I/O privilege level (IOPL) must be equal to 3 to use POPF/POPFD instructions and the VM, RF, IOPL, VIP, and VIF flags are unaffected. If the IOPL is less than 3, the POPF/POPFD instructions cause a general-protection exception (#GP).

See the section titled “EFLAGS Register” in Chapter 3 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for information about the EFLAGS registers.

**Operation**

```
IF VM=0 (* Not in Virtual-8086 Mode *)
   THEN IF CPL=0
      THEN IF OperandSize ← 32;
      THEN
```

</tr>
</tbody>
</table>

Description
Performs a bitwise logical OR operation on the source operand (second operand) and the destination operand (first operand) and stores the result in the destination operand. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register. Each bit of the result is set to 1 if either or both of the corresponding bits of the first and second operands are 1; otherwise, it is set to 0.

Operation
DEST ← DEST OR SRC;

Intel C/C++ Compiler Intrinsic Equivalent

<td>Move data from (m8) closer to the processor using NTA hint.</td>
</tr>
</tbody>
</table>

**Description**

Fetches the line of data from memory that contains the byte specified with the source operand to a location in the cache hierarchy specified by a locality hint:

- **T0** (temporal data)—prefetch data into all cache levels.
- **T1** (temporal data with respect to first level cache)—prefetch data in all cache levels except 0th cache level.
- **T2** (temporal data with respect to second level cache)—prefetch data in all cache levels, except 0th and 1st cache levels.
- **NTA** (non-temporal data with respect to all cache levels)—prefetch data into non-temporal cache structure. (This hint can be used to minimize pollution of caches.)

The source operand is a byte memory location. (The locality hints are encoded into the machine level instruction using bits 3 through 5 of the ModR/M byte. Use of any ModR/M value other than the specified ones will lead to unpredictable behavior.)

If the line selected is already present in the cache hierarchy at a level closer to the processor, no data movement occurs. Prefetches from uncacheable or WC memory are ignored.

The PREFETCH\(h\) instruction is merely a hint and does not affect program behavior. If executed, this instruction moves data closer to the processor in anticipation of future use.

The implementation of prefetch locality hints is implementation-dependent, and can be overloaded or ignored by a processor implementation. The amount of data prefetched is also processor implementation-dependent. It will, however, be a minimum of 32 bytes.

It should be noted that processors are free to speculatively fetch and cache data from system memory regions that are assigned a memory-type that permits speculative reads (that is, the WB, WC, and WT memory types). A PREFETCH\(h\) instruction is considered a hint to this speculative behavior. Because this speculative fetching can occur at any time and is not tied to instruction execution, a PREFETCH\(h\) instruction is not ordered with respect to the fence instructions (MFENCE, SFENCE, and LFENCE) or locked memory references. A PREFETCH\(h\) instruction is also unordered with respect to CLFLUSH instructions, other PREFETCH\(h\) instructions, or any other general instruction. It is ordered with respect to serializing instructions such as CPUID, WRMSR, and OUT, and MOV CR.
PREFETCH—Prefetch (Continued)

Operation
FETCH (m8);

Intel C/C++ Compiler Intrinsic Equivalent
void_mm_prefetch(char *p, int i)

The argument “*p” gives the address of the byte (and corresponding cache line) to be prefetched. The value “i” gives a constant (_MM_HINT_T0, _MM_HINT_T1, _MM_HINT_T2, or _MM_HINT_NTA) that specifies the type of prefetch operation to be performed.

<td>66 0F F6 /r</td>
<td>PSADBW xmm1, xmm2/m128</td>
<td>Computes the absolute differences of the packed unsigned byte integers from xmm2/m128 and xmm1; the 8 low differences and 8 high differences are then summed separately to produce two unsigned word integer results.</td>
</tr>
</tbody>
</table>

Description

Computes the absolute value of the difference of 8 unsigned byte integers from the source operand (first operand) and from the destination operand (second operand). These 8 differences are then summed to produce an unsigned word integer result that is stored in the destination operand. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register. Figure 3-9 shows the operation of the PSADBW instruction when using 64-bit operands.

When operating on 64-bit operands, the word integer result is stored in the low word of the destination operand, and the remaining bytes in the destination operand are cleared to all 0s.

When operating on 128-bit operands, two packed results are computed. Here, the 8 low-order bytes of the source and destination operands are operated on to produce a word result that is stored in the low word of the destination operand, and the 8 high-order bytes are operated on to produce a word result that is stored in bits 64 through 79 of the destination operand. The remaining bytes of the destination operand are cleared to 0s.

PUSHUD—Shuffle Packed Doublewords

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 70 /r lb</td>
<td>PSHUFD xmm1, xmm2/m128, imm8</td>
<td>Shuffle the doublewords in xmm2/m128 based on the encoding in imm8 and store the result in xmm1.</td>
</tr>
</tbody>
</table>

Description

Copies doublewords from source operand (second operand) and inserts them in the destination operand (first operand) at locations selected with the order operand (third operand). Figure 3-10 shows the operation of the PSHUFD instruction and the encoding of the order operand. Each 2-bit field in the order operand selects the contents of one doubleword location in the destination operand. For example, bits 0 and 1 of the order operand selects the contents of doubleword 0 of the destination operand. The encoding of bits 0 and 1 of the order operand (see the field encoding in Figure 3-10) determines which doubleword from the source operand will be copied to doubleword 0 of the destination operand.

![Figure 3-10. PSHUFD Instruction Operation](image)

The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The order operand is an 8-bit immediate.

Note that this instruction permits a doubleword in the source operand to be copied to more than one doubleword location in the destination operand.

Operation

\[

dest[31:0] \leftarrow (src >> (order[1:0] * 32))[31:0] \\

dest[95:64] \leftarrow (src >> (order[5:4] * 32))[31:0] \\

<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F3 0F 70 /r lb</td>
<td>PSHUFHW xmm1, xmm2/m128, imm8</td>
<td>Shuffle the high words in xmm2/m128 based on the encoding in imm8 and store the result in xmm1.</td>
</tr>
</tbody>
</table>

Description
Copies words from the high quadword of the source operand (second operand) and inserts them in the high quadword of the destination operand (first operand) at word locations selected with the order operand (third operand). This operation is similar to the operation used by the PSHUFD instruction, which is illustrated in Figure 3-10. For the PSHUFHW instruction, each 2-bit field in the order operand selects the contents of one word location in the high quadword of the destination operand. The binary encodings of the order operand fields select words (0, 1, 2, or 3) from the high quadword of the source operand to be copied to the destination operand.

The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The order operand is an 8-bit immediate.

Note that this instruction permits a word in the source operand to be copied to more than one word location in the destination operand.

PSHUFLW—Shuffle Packed Low Words

### Description
Copies words from the low quadword of the source operand (second operand) and inserts them in the low quadword of the destination operand (first operand) at word locations selected with the order operand (third operand). This operation is similar to the operation used by the PSHUFD instruction, which is illustrated in Figure 3-10. For the PSHUFLW instruction, each 2-bit field in the order operand selects the contents of one word location in the low quadword of the destination operand. The binary encodings of the order operand fields select words (0, 1, 2, or 3) from the low quadword of the source operand to be copied to the destination operand.

The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The order operand is an 8-bit immediate.

Note that this instruction permits a word in the source operand to be copied to more than one word location in the destination operand.

### Operation

PSLLW/PSLLD/PSLLQ—Shift Packed Data Left Logical

**Description**

Shifts the bits in the individual data elements (words, doublewords, or quadword) in the destination operand (first operand) to the left by the number of bits specified in the count operand (second operand). As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to 0). If the value specified by the count operand is greater than 15 (for words), 31 (for doublewords), or 63 (for a quadword), then the destination operand is set to all 0s. (Figure 3-11 gives an example of shifting words in a 64-bit operand.) The destination operand may be an MMX register or an XMM register; the count operand can be either an MMX register or a 64-bit memory location, an XMM register or a 128-bit memory location, or an 8-bit immediate.

</tbody>
</table>

Description

Shifts the bits in the individual data elements (words or doublewords) in the destination operand (first operand) to the right by the number of bits specified in the count operand (second operand). As the bits in the data elements are shifted right, the empty high-order bits are filled with the initial value of the sign bit of the data element. If the value specified by the count operand is greater than 15 (for words) or 31 (for doublewords), each destination data element is filled with the initial value of the sign bit of the element. (Figure 3-12 gives an example of shifting words in a 64-bit operand.)

![Figure 3-12. PSRAW and PSRAD Instruction Operation Using a 64-bit Operand](image)

The destination operand may be an MMX register or an XMM register; the count operand can be either an MMX register or a 64-bit memory location, an XMM register or a 128-bit memory location, or an 8-bit immediate.
PSRAW/PSRAD—Shift Packed Data Right Arithmetic (Continued)

The PSRAW instruction shifts each of the words in the destination operand to the right by the number of bits specified in the count operand, and the PSRAD instruction shifts each of the doublewords in the destination operand.

Operation

PSRAW instruction with 64-bit operand:
IF (COUNT > 15)
    THEN COUNT ← 16;
FI;
DEST[15..0] ← SignExtend(DEST[15..0] >> COUNT);
* repeat shift operation for 2nd and 3rd words *
DEST[63..48] ← SignExtend(DEST[63..48] >> COUNT);

PSRAD instruction with 64-bit operand:
IF (COUNT > 31)
    THEN COUNT ← 32;
FI;
ELSE
    DEST[31..0] ← SignExtend(DEST[31..0] >> COUNT);
    DEST[63..32] ← SignExtend(DEST[63..32] >> COUNT);

PSRAW instruction with 128-bit operand:
IF (COUNT > 15)
    THEN COUNT ← 16;
FI;
ELSE
    DEST[15-0] ← SignExtend(DEST[15-0] >> COUNT);
* repeat shift operation for 2nd through 7th words *
DEST[127-112] ← SignExtend(DEST[127-112] >> COUNT);

PSRAD instruction with 128-bit operand:
IF (COUNT > 31)
    THEN COUNT ← 32;
FI;
ELSE
    DEST[31-0] ← SignExtend(DEST[31-0] >> COUNT);
* repeat shift operation for 2nd and 3rd doublewords *
DEST[127-96] ← SignExtend(DEST[127-96] >> COUNT);

PSRLW/PSRLD/PSRLQ—Shift Packed Data Right Logical

Description
Shifts the bits in the individual data elements (words, doublewords, or quadword) in the destination operand (first operand) to the right by the number of bits specified in the count operand (second operand). As the bits in the data elements are shifted right, the empty high-order bits are cleared (set to 0). If the value specified by the count operand is greater than 15 (for words), 31 (for doublewords), or 63 (for a quadword), then the destination operand is set to all 0s. (Figure 3-13 gives an example of shifting words in a 64-bit operand.) The destination operand may be an MMX register or an XMM register; the count operand can be either an MMX register or a 64-bit memory location, an XMM register or a 128-bit memory location, or an 8-bit immediate.

Figure 3-13. PSRLW, PSRLD, and PSRLQ Instruction Operation Using 64-bit Operand
INSTRUCTION SET REFERENCE

PSRLW/PSRLD/PSRLQ—Shift Packed Data Right Logical (Continued)

The PSRLW instruction shifts each of the words in the destination operand to the right by the number of bits specified in the count operand; the PSRLD instruction shifts each of the double-words in the destination operand; and the PSRLQ instruction shifts the quadword (or quad-words) in the destination operand.

Operation

PSRLW instruction with 64-bit operand:
IF (COUNT > 15)
THEN
  DEST[64..0] ← 0000000000000000H
ELSE
  DEST[15..0] ← ZeroExtend(Destination[15..0] >> COUNT);
  * repeat shift operation for 2nd and 3rd words *;
  DEST[63..48] ← ZeroExtend(Destination[63..48] >> COUNT);

PSUBB/PSUBW/PSUBD—Subtract Packed Integers

### Description

Performs a SIMD subtract of the packed integers of the source operand (second operand) from the packed integers of the destination operand (first operand), and stores the packed integer results in the destination operand. See Figure 9-4 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a SIMD operation. Overflow is handled with wraparound, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PSUBB instruction subtracts packed byte integers. When an individual result is too large or too small to be represented in a byte, the result is wrapped around and the low 8 bits are written to the destination element.

The PSUBW instruction subtracts packed word integers. When an individual result is too large or too small to be represented in a word, the result is wrapped around and the low 16 bits are written to the destination element.

The PSUBD instruction subtracts packed doubleword integers. When an individual result is too large or too small to be represented in a doubleword, the result is wrapped around and the low 32 bits are written to the destination element.

Note that the PSUBB, PSUBW, and PSUBD instructions can operate on either unsigned or signed (two’s complement notation) packed integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of values operated on.

#AC(0) (64-bit operations only.) If alignment checking is enabled and an unaligned memory reference is made.
PSUBB/PSUBW/PSUBD—Subtract Packed Integers (Continued)

Numeric Exceptions

None.
PSUBQ—Subtract Packed Quadword Integers

Description
Subtracts the second operand (source operand) from the first operand (destination operand) and stores the result in the destination operand. The source operand can be a quadword integer stored in an MMX register or a 64-bit memory location, or it can be two packed quadword integers stored in an XMM register or an 128-bit memory location. The destination operand can be a quadword integer stored in an MMX register or two packed quadword integers stored in an XMM register. When packed quadword operands are used, a SIMD subtract is performed. When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

Note that the PSUBQ instruction can operate on either unsigned or signed (two’s complement notation) integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of the values operated on.

Operation
PSUBQ instruction with 64-Bit operands:
DEST[63-0] ← DEST[63-0] – SRC[63-0];

PSUBQ instruction with 128-Bit operands:
DEST[63-0] ← DEST[63-0] – SRC[63-0];
DEST[127-64] ← DEST[127-64] – SRC[127-64];

</tr>
</tbody>
</table>

Description

Performs a SIMD subtract of the packed signed integers of the source operand (second operand) from the packed signed integers of the destination operand (first operand), and stores the packed integer results in the destination operand. See Figure 9-4 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a SIMD operation. Overflow is handled with signed saturation, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PSUBSB instruction subtracts packed signed byte integers. When an individual byte result is beyond the range of a signed byte integer (that is, greater than 7FH or less than 80H), the saturated value of 7FH or 80H, respectively, is written to the destination operand.

The PSUBSW instruction subtracts packed signed word integers. When an individual word result is beyond the range of a signed word integer (that is, greater than 7FFFH or less than 8000H), the saturated value of 7FFFH or 8000H, respectively, is written to the destination operand.

Operation

PSUBSB instruction with 64-bit operands:

```
DEST[7..0] ← SaturateToSignedByte(DEST[7..0] − SRC[7..0]) ;
* repeat subtract operation for 2nd through 7th bytes *;
DEST[63..56] ← SaturateToSignedByte(DEST[63..56] − SRC[63..56]) ;
```
PSUBSB/PSUBSW—Subtract Packed Signed Integers with Signed Saturation (Continued)

PSUBSB instruction with 128-bit operands:
DEST[7-0] ← SaturateToSignedByte (DEST[7-0] – SRC[7-0]);
* repeat subtract operation for 2nd through 14th bytes *;

PSUBSW instruction with 64-bit operands
DEST[15..0] ← SaturateToSignedWord(DEST[15..0] – SRC[15..0] );
* repeat subtract operation for 2nd and 7th words *;
DEST[63..48] ← SaturateToSignedWord(DEST[63..48] – SRC[63..48] );

PSUBSW instruction with 128-bit operands
* repeat subtract operation for 2nd through 7th words *;

Numeric Exceptions

None.
PSUBUSB/PSUBUSW—Subtract Packed Unsigned Integers with Unsigned Saturation

**Description**

Performs a SIMD subtract of the packed unsigned integers of the source operand (second operand) from the packed unsigned integers of the destination operand (first operand), and stores the packed unsigned integer results in the destination operand. See Figure 9-4 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a SIMD operation. Overflow is handled with unsigned saturation, as described in the following paragraphs.

These instructions can operate on either 64-bit or 128-bit operands. When operating on 64-bit operands, the destination operand must be an MMX register and the source operand can be either an MMX register or a 64-bit memory location. When operating on 128-bit operands, the destination operand must be an XMM register and the source operand can be either an XMM register or a 128-bit memory location.

The PSUBUSB instruction subtracts packed unsigned byte integers. When an individual byte result is less than zero, the saturated value of 00H is written to the destination operand.

The PSUBUSW instruction subtracts packed unsigned word integers. When an individual word result is less than zero, the saturated value of 0000H is written to the destination operand.

**Operation**

**PSUBUSB instruction with 64-bit operands:**

\[
\text{DEST}[7..0] \leftarrow \text{SaturateToUnsignedByte}(\text{DEST}[7..0] - \text{SRC}[7..0]); \\
\]

* repeat add operation for 2nd through 7th bytes *

\[
\text{DEST}[63..56] \leftarrow \text{SaturateToUnsignedByte}(\text{DEST}[63..56] - \text{SRC}[63..56])
\]

**PSUBUSB instruction with 128-bit operands:**

\[
\text{DEST}[7-0] \leftarrow \text{SaturateToUnsignedByte} (\text{DEST}[7-0] - \text{SRC}[7-0]); \\
\]

* repeat add operation for 2nd through 14th bytes *

\[
\text{DEST}[127-120] \leftarrow \text{SaturateToUnSignedByte} (\text{DEST}[127-120] - \text{SRC}[127-120]);
\]

<td>PUNPCKHQDQ xmm1, xmm2/m128</td>
<td>Unpack and interleave high-order quadwords from xmm1 and xmm2/m128 into xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Unpacks and interleaves the high-order data elements (bytes, words, doublewords, or quadwords) of the destination operand (first operand) and source operand (second operand) into the destination operand. (Figure 3-14 shows the unpack operation for bytes in 64-bit operands.). The low-order data elements are ignored.

![Figure 3-14. PUNPCKHBW Instruction Operation Using 64-bit Operands](image)

The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register. When the source data comes from a 64-bit memory operand, the full 64-bit operand is accessed from memory, but the instruction uses only the high-order 32 bits. When the source data comes from a 128-bit memory operand, a processor implementation may fetch only the appropriate 64 bits from memory. Alignment to 16-byte boundary and normal segment checking will still be enforced.
PUNPCKHBW/PUNPCKHWD/PUNPCKHDQ/PUNPCKHQDQ—
Unpack High Data (Continued)

The PUNPCKHBW instruction interleaves the high-order bytes of the source and destination operands, the PUNPCKHWD instruction interleaves the high-order words of the source and destination operands, the PUNPCKHDQ instruction interleaves the high-order doubleword (or doublewords) of the source and destination operands, and the PUNPCKHQDQ instruction interleaves the high-order quadwords of the source and destination operands.

These instructions can be used to convert bytes to words, words to doublewords, doublewords to quadwords, and quadwords to double quadwords, respectively, by placing all 0s in the source operand. Here, if the source operand contains all 0s, the result (stored in the destination operand) contains zero extensions of the high-order data elements from the original value in the destination operand. For example, with the PUNPCKHBW instruction the high-order bytes are zero extended (that is, unpacked into unsigned word integers), and with the PUNPCKHWD instruction, the high-order words are zero extended (unpacked into unsigned doubleword integers).

Operation

PUNPCKHBW instruction with 64-bit operands:
\[
\begin{align*}
\text{DEST}[7..0] & \leftarrow \text{DEST}[39..32]; \\
\text{DEST}[15..8] & \leftarrow \text{SRC}[39..32]; \\
\text{DEST}[23..16] & \leftarrow \text{DEST}[47..40]; \\
\text{DEST}[31..24] & \leftarrow \text{SRC}[47..40]; \\
\text{DEST}[39..32] & \leftarrow \text{DEST}[55..48]; \\

</tbody>
</table>

**Description**

Unpacks and interleaves the low-order data elements (bytes, words, doublewords, and quadwords) of the destination operand (first operand) and source operand (second operand) into the destination operand. (Figure 3-15 shows the unpack operation for bytes in 64-bit operands.). The high-order data elements are ignored.

![Figure 3-15. PUNPCKLBW Instruction Operation Using 64-bit Operands](image)

The source operand can be an MMX register or a 64-bit memory location, or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX or an XMM register. When the source data comes from a 64-bit memory operand, the full 64-bit operand is accessed from memory, but the instruction uses only the high-order 32 bits. When the source data comes from a 128-bit memory operand, a processor implementation may fetch only the appropriate 64 bits from memory. Alignment to 16-byte boundary and normal segment checking will still be enforced.
PUNPCKLBW/PUNPCKLWD/PUNPCKLDQ/PUNPCKLQDQ—Unpack Low Data (Continued)

The PUNPCKLBW instruction interleaves the low-order bytes of the source and destination operands, the PUNPCKLWD instruction interleaves the low-order words of the source and destination operands, the PUNPCKLDQ instruction interleaves the low-order doubleword (or doublewords) of the source and destination operands, and the PUNPCKLQDQ instruction interleaves the low-order quadwords of the source and destination operands.

These instructions can be used to convert bytes to words, words to doublewords, doublewords to quadwords, and quadwords to double quadwords, respectively, by placing all 0s in the source operand. Here, if the source operand contains all 0s, the result (stored in the destination operand) contains zero extensions of the high-order data elements from the original value in the destination operand. For example, with the PUNPCKLBW instruction the high-order bytes are zero extended (that is, unpacked into unsigned word integers), and with the PUNPCKLWD instruction, the high-order words are zero extended (unpacked into unsigned doubleword integers).

Operation

PUNPCKLBW instruction with 64-bit operands:

\[
\begin{align*}
\text{DEST}[63..56] & \leftarrow \text{SRC}[31..24]; \\
\text{DEST}[55..48] & \leftarrow \text{DEST}[31..24]; \\
\text{DEST}[47..40] & \leftarrow \text{SRC}[23..16]; \\
\text{DEST}[39..32] & \leftarrow \text{DEST}[23..16]; \\
\text{DEST}[31..24] & \leftarrow \text{SRC}[15..8]; \\
\text{DEST}[23..16] & \leftarrow \text{DEST}[15..8]; \\
\text{DEST}[15..8] & \leftarrow \text{SRC}[7..0]; \\
\text{DEST}[7..0] & \leftarrow \text{DEST}[7..0];
\end{align*}
\]

PUNPCKLWD instruction with 64-bit operands:

\[
\begin{align*}
\text{DEST}[63..48] & \leftarrow \text{SRC}[31..16]; \\
\text{DEST}[47..32] & \leftarrow \text{DEST}[31..16]; \\
\text{DEST}[31..16] & \leftarrow \text{SRC}[15..0]; \\

Description

Decrement the stack pointer and then stores the source operand on the top of the stack. The address-size attribute of the stack segment determines the stack pointer size (16 bits or 32 bits), and the operand-size attribute of the current code segment determines the amount the stack pointer is decremented (2 bytes or 4 bytes). For example, if these address- and operand-size attributes are 32, the 32-bit ESP register (stack pointer) is decremented by 4 and, if they are 16, the 16-bit SP register is decremented by 2. (The B flag in the stack segment’s segment descriptor determines the stack’s address-size attribute, and the D flag in the current code segment’s segment descriptor, along with prefixes, determines the operand-size attribute and also the address-size attribute of the source operand.) Pushing a 16-bit operand when the stack address-size attribute is 32 can result in a misaligned the stack pointer (that is, the stack pointer is not aligned on a doubleword boundary).

The PUSH ESP instruction pushes the value of the ESP register as it existed before the instruction was executed. Thus, if a PUSH instruction uses a memory operand in which the ESP register is used as a base register for computing the operand address, the effective address of the operand is computed before the ESP register is decremented.

In the real-address mode, if the ESP or SP register is 1 when the PUSH instruction is executed, the processor shuts down due to a lack of stack space. No exception is generated to indicate this condition.

IA-32 Architecture Compatibility

For IA-32 processors from the Intel 286 on, the PUSH ESP instruction pushes the value of the ESP register as it existed before the instruction was executed. (This is also true in the real-address and virtual-8086 modes.) For the Intel 8086 processor, the PUSH SP instruction pushes the new value of the SP register (that is the value after it has been decremented by 2).

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
PUSHA/PUSHAD—Push All General-Purpose Registers

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>PUSHA</td>
<td>Push AX, CX, DX, BX, original SP, BP, SI, and DI</td>
</tr>
<tr>
<td>60</td>
<td>PUSHAD</td>
<td>Push EAX, ECX, EDX, EBX, original ESP, EBP, ESI, and EDI</td>
</tr>
</tbody>
</table>

**Description**

Pushes the contents of the general-purpose registers onto the stack. The registers are stored on the stack in the following order: EAX, ECX, EDX, EBX, EBP, ESP (original value), EBP, ESI, and EDI (if the current operand-size attribute is 32) and AX, CX, DX, BX, SP (original value), BP, SI, and DI (if the operand-size attribute is 16). These instructions perform the reverse operation of the POPA/POPAD instructions. The value pushed for the ESP or SP register is its value before prior to pushing the first register (see the “Operation” section below).

The PUSHA (push all) and PUSHAD (push all double) mnemonics reference the same opcode. The PUSHA instruction is intended for use when the operand-size attribute is 16 and the PUSHAD instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when PUSHA is used and to 32 when PUSHAD is used. Others may treat these mnemonics as synonyms (PUSHA/PUSHAD) and use the current setting of the operand-size attribute to determine the size of values to be pushed from the stack, regardless of the mnemonic used.

In the real-address mode, if the ESP or SP register is 1, 3, or 5 when the PUSHA/PUSHAD instruction is executed, the processor shuts down due to a lack of stack space. No exception is generated to indicate this condition.

**Operation**

IF OperandSize ← 32 (* PUSHA instruction *)
THEN
    Temp ← (ESP);
    Push(EAX);
    Push(ECX);
    Push(EDX);
    Push(EBX);
    Push(Temp);
    Push(EBP);
    Push(ESI);
    Push(EDI);
ELSE (* OperandSize ← 16, PUSHA instruction *)
    Temp ← (SP);
    Push(AX);
    Push(CX);
    Push(DX);
    Push(BX);
    Push(Temp);
PUSHA/PUSHAD—Push All General-Purpose Register (Continued)

Push(BP);
Push(SI);
Push(DI);
Fl;

Flags Affected
None.

Protected Mode Exceptions
#SS(0) If the starting or ending stack address is outside the stack segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If an unaligned memory reference is made while the current privilege level is 3 and alignment checking is enabled.

Real-Address Mode Exceptions
#GP If the ESP or SP register contains 7, 9, 11, 13, or 15.

Virtual-8086 Mode Exceptions
#GP(0) If the ESP or SP register contains 7, 9, 11, 13, or 15.
#PF(fault-code) If a page fault occurs.
#AC(0) If an unaligned memory reference is made while alignment checking is enabled.
PUSHF/PUSHFD—Push EFLAGS Register onto the Stack

**Description**

Decrements the stack pointer by 4 (if the current operand-size attribute is 32) and pushes the entire contents of the EFLAGS register onto the stack, or decrements the stack pointer by 2 (if the operand-size attribute is 16) and pushes the lower 16 bits of the EFLAGS register (that is, the FLAGS register) onto the stack. (These instructions reverse the operation of the POPF/POPFD instructions.) When copying the entire EFLAGS register to the stack, the VM and RF flags (bits 16 and 17) are not copied; instead, the values for these flags are cleared in the EFLAGS image stored on the stack. See the section titled “EFLAGS Register” in Chapter 3 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for information about the EFLAGS registers.

The PUSHF (push flags) and PUSHFD (push flags double) mnemonics reference the same opcode. The PUSHF instruction is intended for use when the operand-size attribute is 16 and the PUSHFD instruction for when the operand-size attribute is 32. Some assemblers may force the operand size to 16 when PUSHF is used and to 32 when PUSHFD is used. Others may treat these mnemonics as synonyms (PUSHF/PUSHFD) and use the current setting of the operand-size attribute to determine the size of values to be pushed from the stack, regardless of the mnemonic used.

When in virtual-8086 mode and the I/O privilege level (IOPL) is less than 3, the PUSHF/PUSHFD instruction causes a general protection exception (#GP).

In the real-address mode, if the ESP or SP register is 1, 3, or 5 when the PUSHA/PUSHAD instruction is executed, the processor shuts down due to a lack of stack space. No exception is generated to indicate this condition.

**Operation**

```
IF (PE=0) OR (PE=1 AND ((VM=0) OR (VM=1 AND IOPL=3)))
(* Real-Address Mode, Protected mode, or Virtual-8086 mode with IOPL equal to 3 *)
THEN
  IF OperandSize ← 32
  THEN
    push(EFLAGS AND 00FCFFFFH); (* VM and RF EFLAG bits are cleared in image stored on the stack*)
    ELSE
      push(EFLAGS); (* Lower 16 bits only *)
  FI;
```

<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F EF /r</td>
<td>PXOR mm, mm/m64</td>
<td>Bitwise XOR of mm/m64 and mm.</td>
</tr>
<tr>
<td>66 0F EF /r</td>
<td>PXOR xmm1, xmm2/m128</td>
<td>Bitwise XOR of xmm2/m128 and xmm1.</td>
</tr>
</tbody>
</table>

**Description**

Performs a bitwise logical exclusive-OR (XOR) operation on the source operand (second operand) and the destination operand (first operand) and stores the result in the destination operand. The source operand can be an MMX register or a 64-bit memory location or it can be an XMM register or a 128-bit memory location. The destination operand can be an MMX register or an XMM register. Each bit of the result is 1 if the corresponding bits of the two operands are different; each bit is 0 if the corresponding bits of the operands are the same.

**Operation**

DEST ← DEST XOR SRC;

**Intel C/C++ Compiler Intrinsic Equivalent**

</table>
RCL/RCR/ROL/ROR—Rotate (Continued)

Description
Shifts (rotates) the bits of the first operand (destination operand) the number of bit positions specified in the second operand (count operand) and stores the result in the destination operand. The destination operand can be a register or a memory location; the count operand is an unsigned integer that can be an immediate or a value in the CL register. The processor restricts the count to a number between 0 and 31 by masking all the bits in the count operand except the 5 least-significant bits.

The rotate left (ROL) and rotate through carry left (RCL) instructions shift all the bits toward more-significant bit positions, except for the most-significant bit, which is rotated to the least-significant bit location (see Figure 7-11 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1). The rotate right (ROR) and rotate through carry right (RCR) instructions shift all the bits toward less significant bit positions, except for the least-significant bit, which is rotated to the most-significant bit location (see Figure 7-11 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1).

The RCL and RCR instructions include the CF flag in the rotation. The RCL instruction shifts the CF flag into the least-significant bit and shifts the most-significant bit into the CF flag (see Figure 7-11 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). The RCR instruction shifts the CF flag into the most-significant bit and shifts the least-significant bit into the CF flag (see Figure 7-11 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1). For the ROL and ROR instructions, the original value of the CF flag is not a part of the result, but the CF flag receives a copy of the bit that was shifted from one end to the other.

The OF flag is defined only for the 1-bit rotates; it is undefined in all other cases (except that a zero-bit rotate does nothing, that is affects no flags). For left rotates, the OF flag is set to the exclusive OR of the CF bit (after the rotate) and the most-significant bit of the result. For right rotates, the OF flag is set to the exclusive OR of the two most-significant bits of the result.

IA-32 Architecture Compatibility
The 8086 does not mask the rotation count. However, all other IA-32 processors (starting with the Intel 286 processor) do mask the rotation count to 5 bits, resulting in a maximum count of 31. This masking is done in all operating modes (including the virtual-8086 mode) to reduce the maximum execution time of the instructions.

Operation
(* RCL and RCR instructions *)
SIZE ← OperandSize
CASE (determine count) OF
  SIZE ← 8:  tempCOUNT ← (COUNT AND 1FH) MOD 9;
  SIZE ← 16: tempCOUNT ← (COUNT AND 1FH) MOD 17;
  SIZE ← 32: tempCOUNT ← COUNT AND 1FH;
ESAC;
RCL/RCR/ROL/ROR—Rotate (Continued)

(* RCL instruction operation *)
WHILE (tempCOUNT ≠ 0)
  DO
    tempCF ← MSB(DEST);
    tempCOUNT ← tempCOUNT − 1;
    tempCF ← tempCF;
    tempCF ← tempCF;
  OD;
ELIHW;
IF COUNT ← 1
  THEN OF ← MSB(DEST) XOR CF;
  ELSE OF is undefined;

CF ← MSB(DEST);
IF COUNT ← 1
  THEN OF ← MSB(DEST) XOR MSB − 1(DEST);
  ELSE OF is undefined;
FI;

Flags Affected
The CF flag contains the value of the bit shifted into it. The OF flag is affected only for single-bit rotates (see “Description” above); it is undefined for multi-bit rotates. The SF, ZF, AF, and PF flags are not affected.

Protected Mode Exceptions
#GP(0) If the source operand is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.
RCL/RCR/ROL/ROR—Rotate (Continued)

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
RCPPS—Compute Reciprocals of Packed Single-Precision Floating-Point Values

**Description**

Performs a SIMD computation of the approximate reciprocals of the four packed single-precision floating-point values in the source operand (second operand) stores the packed single-precision floating-point results in the destination operand. The maximum relative error for this approximation is \( \leq 1.5 \times 2^{-12} \). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 10-5 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a SIMD single-precision floating-point operation.

The RCPSS instruction is not affected by the rounding control bits in the MXCSR register. When a source value is a 0.0, an \( \infty \) of the sign of the source value is returned. A denormal source value is treated as a 0.0 (of the same sign). Underflow results are always flushed to 0.0, with the sign of the operand. When a source value is an SNaN or QNaN, the SNaN converted to a QNaN or the source QNaN is returned.

**Operation**

\[
\begin{align*}
\text{DEST}[31-0] & \leftarrow \text{APPROXIMATE}(1.0/(\text{SRC}[31-0])); \\
\text{DEST}[63-32] & \leftarrow \text{APPROXIMATE}(1.0/(\text{SRC}[63-32])); \\
\text{DEST}[95-64] & \leftarrow \text{APPROXIMATE}(1.0/(\text{SRC}[95-64])); \\
\text{DEST}[127-96] & \leftarrow \text{APPROXIMATE}(1.0/(\text{SRC}[127-96]));
\end{align*}
\]

**Intel C/C++ Compiler Intrinsic Equivalent**

#PF(fault-code) For a page fault.
#NM If TS in CR0 is set.
#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
   If EM in CR0 is set.
   If OSFXSR in CR4 is 0.
   If CPUID feature flag SSE is 0.

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.
Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.
#NM If TS in CR0 is set.
#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
   If EM in CR0 is set.
   If OSFXSR in CR4 is 0.
   If CPUID feature flag SSE is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode
#PF(fault-code) For a page fault.
RCPSS—Compute Reciprocal of Scalar Single-Precision Floating-Point Values

Description
Computes an approximate reciprocal of the low single-precision floating-point value in the source operand (second operand) and stores the single-precision floating-point result in the destination operand. The maximum relative error for this approximation is (≤1.5 * 2^{-12}). The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The three high-order doublewords of the destination operand remain unchanged. See Figure 10-6 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1 for an illustration of a scalar single-precision floating-point operation.

The RCPSS instruction is not affected by the rounding control bits in the MXCSR register. When a source value is 0.0, an ∞ of the sign of the source value is returned. A denormal source value is treated as a 0.0 (of the same sign). Underflow results are always flushed to 0.0, with the sign of the operand. When a source value is an SNaN or QNaN, the SNaN converted to a QNaN or the source QNaN is returned.

Operation
\[
\text{DEST}[31-0] \leftarrow \text{APPROX}(1.0/(\text{SRC}[31-0])); \\
* \text{DEST}[127-32] \text{ remains unchanged }*;
\]

RDMSR—Read from Model Specific Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 32</td>
<td>RDMSR</td>
<td>Load MSR specified by ECX into EDX:EAX</td>
</tr>
</tbody>
</table>

**Description**

Loads the contents of a 64-bit model specific register (MSR) specified in the ECX register into registers EDX:EAX. The input value loaded into the ECX register is the address of the MSR to be read. The EDX register is loaded with the high-order 32 bits of the MSR and the EAX register is loaded with the low-order 32 bits. If less than 64 bits are implemented in the MSR being read, the values returned to EDX:EAX in unimplemented bit locations are undefined.

This instruction must be executed at privilege level 0 or in real-address mode; otherwise, a general protection exception #GP(0) will be generated. Specifying a reserved or unimplemented MSR address in ECX will also cause a general protection exception.

The MSRs control functions for testability, execution tracing, performance-monitoring and machine check errors. Appendix B, Model-Specific Registers (MSRs), in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, lists all the MSRs that can be read with this instruction and their addresses. Note that each processor family has its own set of MSRs.

The CPUID instruction should be used to determine whether MSRs are supported (EDX[5]=1) before using this instruction.

**IA-32 Architecture Compatibility**

The MSRs and the ability to read them with the RDMSR instruction were introduced into the IA-32 Architecture with the Pentium processor. Execution of this instruction by an IA-32 processor earlier than the Pentium processor results in an invalid opcode exception #UD.

**Operation**

EDX:EAX ← MSR[ECX];

**Flags Affected**

None.

**Protected Mode Exceptions**

#GP(0) If the current privilege level is not 0.

If the value in ECX specifies a reserved or unimplemented MSR address.

**Real-Address Mode Exceptions**

#GP If the value in ECX specifies a reserved or unimplemented MSR address.
RDMSR—Read from Model Specific Register (Continued)

Virtual-8086 Mode Exceptions

#GP(0) The RDMSR instruction is not recognized in virtual-8086 mode.
RDP MC—Read Performance-Monitoring Counters

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 33</td>
<td>RDP MC</td>
<td>Read performance-monitoring counter specified by ECX into EDX:EAX</td>
</tr>
</tbody>
</table>

Description

Loads the contents of the 40-bit performance-monitoring counter specified in the ECX register into registers EDX:EAX. The EDX register is loaded with the high-order 8 bits of the counter and the EAX register is loaded with the low-order 32 bits. The counter to be read is specified with an unsigned integer placed in the ECX register. The P6 processors have two performance-monitoring counters (0 and 1), which are specified by placing 0000H or 0001H, respectively, in the ECX register. The Pentium 4 processors have 18 counters (0 through 17), which are specified with 0000H through 0011H, respectively.

The Pentium 4 processors also support “fast” (32-bit) and “slow” (40-bit) reads of the performance counters, selected with bit 31 of the ECX register. If bit 31 is set, the RDP MC instruction reads only the low 32 bits of the selected performance counter; if bit 31 is clear, all 40 bits of the counter are read. The 32-bit counter result is returned in the EAX register, and the EDX register is set to 0. A 32-bit read executes faster on a Pentium 4 processor than a full 40-bit read.

The RDP MC instruction allows application code running at a privilege level of 1, 2, or 3 to read the performance-monitoring counters if the PCE flag in the CR4 register is set. This instruction is provided to allow performance monitoring by application code without incurring the overhead of a call to an operating-system procedure.

The performance-monitoring counters are event counters that can be programmed to count events such as the number of instructions decoded, number of interrupts received, or number of cache loads. Appendix A, Performance-Monitoring Events, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, lists the events that can be counted for the Pentium 4 earlier IA-32 processors.

The RDP MC instruction is not a serialize instruction; that is, it does not imply that all the events caused by the preceding instructions have been completed or that events caused by subsequent instructions have not begun. If an exact event count is desired, software must insert a serializing instruction (such as the CPUID instruction) before and/or after the RDP MC instruction.

In the Pentium 4 processors, performing back-to-back fast reads are not guaranteed to be monotonic. To guarantee monotonicity on back-to-back reads, a serializing instruction must be placed between the two RDP MC instructions.

The RDP MC instruction can execute in 16-bit addressing mode or virtual-8086 mode; however, the full contents of the ECX register are used to select the counter, and the event count is stored in the full EAX and EDX registers.

The RDP MC instruction was introduced into the IA-32 Architecture in the Pentium Pro processor and the Pentium processor with MMX technology. The earlier Pentium processors have performance-monitoring counters, but they must be read with the RDMSR instruction.
RDPMC—Read Performance-Monitoring Counters (Continued)

Operation

(* P6 and Pentium with MMX processors *)

IF (ECX = 0 OR 1) AND ((CR4.PCE = 1) OR ((CR4.PCE = 0) AND (CPL= 0)))
   THEN
      EAX ← PMC(ECX)[31:0];
      EDX ← PMC(ECX)[39:32];

      #GP(0); Fl;

(* Pentium 4 processors *)

IF (ECX = 0...17) AND ((CR4.PCE = 1) OR ((CR4.PCE = 0) AND (CPL=0 )))
   THEN IF ECX[31] = 0
      THEN EAX ← PMC(ECX)[31:0]; (* 40-bit read *);
          EDX ← PMC(ECX)[39:32];
      ELSE IF ECX[31] = 1
          THEN EAX ← PMC(ECX)[31:0]; (* 32-bit read *);
              EDX ← 0;
      FI;
   ELSE (* ECX ≠ 0...17 and/or CR4.PCE is 0 and CPL is 1, 2, or 3 *)
      #GP(0); Fl;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0 and the PCE flag in the CR4 register is clear.
If the value in the ECX register is not 0 or 1.

Real-Address Mode Exceptions

#GP If the PCE flag in the CR4 register is clear.
If the value in the ECX register is not 0 or 1.

Virtual-8086 Mode Exceptions

#GP(0) If the PCE flag in the CR4 register is clear.
If the value in the ECX register is not 0 or 1.
RDTSC—Read Time-Stamp Counter

Description

Loads the current value of the processor’s time-stamp counter into the EDX:EAX registers. The time-stamp counter is contained in a 64-bit MSR. The high-order 32 bits of the MSR are loaded into the EDX register, and the low-order 32 bits are loaded into the EAX register. The processor increments the time-stamp counter MSR every clock cycle and resets it to 0 whenever the processor is reset.

The time stamp disable (TSD) flag in register CR4 restricts the use of the RDTSC instruction. When the TSD flag is clear, the RDTSC instruction can be executed at any privilege level; when the flag is set, the instruction can only be executed at privilege level 0. The time-stamp counter can also be read with the RDMSR instruction, when executing at privilege level 0.

The RDTSC instruction is not a serializing instruction. Thus, it does not necessarily wait until all previous instructions have been executed before reading the counter. Similarly, subsequent instructions may begin execution before the read operation is performed.

This instruction was introduced into the IA-32 Architecture in the Pentium processor.

Operation

IF (CR4.TSD ← 0) OR ((CR4.TSD ← 1) AND (CPL=0))
THEN
    EDX:EAX ← TimeStampCounter;
ELSE (* CR4 is 1 and CPL is 1, 2, or 3 *)
    #GP(0)
FI;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If the TSD flag in register CR4 is set and the CPL is greater than 0.

Real-Address Mode Exceptions

#GP If the TSD flag in register CR4 is set.

Virtual-8086 Mode Exceptions

#GP(0) If the TSD flag in register CR4 is set.

</tbody>
</table>

Description

Repeats a string instruction the number of times specified in the count register ((E)CX) or until the indicated condition of the ZF flag is no longer met. The REP (repeat), REPE (repeat while equal), REPNE (repeat while not equal), REPZ (repeat while zero), and REPNZ (repeat while not zero) mnemonics are prefixes that can be added to one of the string instructions. The REP prefix can be added to the INS, OUTS, MOVSB, LODSB, and STOS instructions, and the REPE, REPNE, REPZ, and REPNZ prefixes can be added to the CMPS and SCAS instructions. (The REPZ and REPNZ prefixes are synonymous forms of the REPE and REPNE prefixes, respectively.) The behavior of the REP prefix is undefined when used with non-string instructions.

The REP prefixes apply only to one string instruction at a time. To repeat a block of instructions, use the LOOP instruction or another looping construct.
REP/REPE/REPZ/REPNE/REPNZ—Repeat String Operation Prefix (Continued)

All of these repeat prefixes cause the associated instruction to be repeated until the count in register (E)CX is decremented to 0 (see the following table). (If the current address-size attribute is 32, register ECX is used as a counter, and if the address-size attribute is 16, the CX register is used.) The REPE, REPNE, REPZ, and REPNZ prefixes also check the state of the ZF flag after each iteration and terminate the repeat loop if the ZF flag is not in the specified state. When both termination conditions are tested, the cause of a repeat termination can be determined either by testing the (E)CX register with a JECXZ instruction or by testing the ZF flag with a JZ, JNZ, and JNE instruction.

<table>
<thead>
<tr>
<th>Repeat Prefix</th>
<th>Termination Condition 1</th>
<th>Termination Condition 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>REP</td>
<td>ECX=0</td>
<td>None</td>
</tr>
<tr>
<td>REPE/REPZ</td>
<td>ECX=0</td>
<td>ZF=0</td>
</tr>
<tr>
<td>REPNE/REPNZ</td>
<td>ECX=0</td>
<td>ZF=1</td>
</tr>
</tbody>
</table>

When the REPE/REPZ and REPNE/REPNZ prefixes are used, the ZF flag does not require initialization because both the CMPS and SCAS instructions affect the ZF flag according to the results of the comparisons they make.

A repeating string operation can be suspended by an exception or interrupt. When this happens, the state of the registers is preserved to allow the string operation to be resumed upon a return from the exception or interrupt handler. The source and destination registers point to the next string elements to be operated on, the EIP register points to the string instruction, and the ECX register has the value it held following the last successful iteration of the instruction. This mechanism allows long string operations to proceed without affecting the interrupt response time of the system.

When a fault occurs during the execution of a CMPS or SCAS instruction that is prefixed with REPE or REPNE, the EFLAGS value is restored to the state prior to the execution of the instruction. Since the SCAS and CMPS instructions do not use EFLAGS as an input, the processor can resume the instruction after the page fault handler.

Use the REP INS and REP OUTS instructions with caution. Not all I/O ports can handle the rate at which these instructions execute.

A REP STOS instruction is the fastest way to initialize a large block of memory.

Flags Affected
None; however, the CMPS and SCAS instructions do set the status flags in the EFLAGS register.

Exceptions (All Operating Modes)
None; however, exceptions can be generated by the instruction a repeat prefix is associated with.
RET—Return from Procedure

Description

Transfers program control to a return address located on the top of the stack. The address is usually placed on the stack by a CALL instruction, and the return is made to the instruction that follows the CALL instruction.

The optional source operand specifies the number of stack bytes to be released after the return address is popped; the default is none. This operand can be used to release parameters from the stack that were passed to the called procedure and are no longer needed. It must be used when the CALL instruction used to switch to a new procedure uses a call gate with a non-zero word count to access the new procedure. Here, the source operand for the RET instruction must specify the same number of bytes as is specified in the word count field of the call gate.

The RET instruction can be used to execute three different types of returns:

- Near return—A return to a calling procedure within the current code segment (the segment currently pointed to by the CS register), sometimes referred to as an intrasegment return.
- Far return—A return to a calling procedure located in a different segment than the current code segment, sometimes referred to as an intersegment return.
- Inter-privilege-level far return—A far return to a different privilege level than that of the currently executing program or procedure.

The inter-privilege-level return type can only be executed in protected mode. See the section titled “Calling Procedures Using Call and RET” in Chapter 6 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, for detailed information on near, far, and inter-privilege-level returns.

When executing a near return, the processor pops the return instruction pointer (offset) from the top of the stack into the EIP register and begins program execution at the new instruction pointer. The CS register is unchanged.

When executing a far return, the processor pops the return instruction pointer from the top of the stack into the EIP register, then pops the segment selector from the top of the stack into the CS register. The processor then begins program execution in the new code segment at the new instruction pointer.
RET—Return from Procedure (Continued)

The mechanics of an inter-privilege-level far return are similar to an intersegment return, except that the processor examines the privilege levels and access rights of the code and stack segments being returned to determine if the control transfer is allowed to be made. The DS, ES, FS, and GS segment registers are cleared by the RET instruction during an inter-privilege-level return if they refer to segments that are not allowed to be accessed at the new privilege level. Since a stack switch also occurs on an inter-privilege level return, the ESP and SS registers are loaded from the stack.

If parameters are passed to the called procedure during an inter-privilege level call, the optional source operand must be used with the RET instruction to release the parameters on the return. Here, the parameters are released both from the called procedure’s stack and the calling procedure’s stack (that is, the stack being returned to).

Operation

(* Near return *)

Virtual-8086 Mode Exceptions

#GP(0) If the return instruction pointer is not within the return code segment limit.

#SS(0) If the top bytes of stack are not within stack limits.

#PF(fault-code) If a page fault occurs.

#AC(0) If an unaligned memory access occurs when alignment checking is enabled.
ROL/ROR—Rotate
See entry for RCL/RCR/ROL/ROR—Rotate.
RSM—Resume from System Management Mode

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F AA</td>
<td>RSM</td>
<td>Resume operation of interrupted program</td>
</tr>
</tbody>
</table>

**Description**

Returns program control from system management mode (SMM) to the application program or operating-system procedure that was interrupted when the processor received an SSM interrupt. The processor’s state is restored from the dump created upon entering SMM. If the processor detects invalid state information during state restoration, it enters the shutdown state. The following invalid information can cause a shutdown:

- Any reserved bit of CR4 is set to 1.
- Any illegal combination of bits in CR0, such as (PG=1 and PE=0) or (NW=1 and CD=0).
- (Intel Pentium and Intel486 processors only.) The value stored in the state dump base field is not a 32-KByte aligned address.

The contents of the model-specific registers are not affected by a return from SMM.

**Operation**

ReturnFromSSM;
ProcessorState ← Restore(SSMDump);

**Flags Affected**

All.

**Protected Mode Exceptions**

#UD If an attempt is made to execute this instruction when the processor is not in SMM.

**Real-Address Mode Exceptions**

#UD If an attempt is made to execute this instruction when the processor is not in SMM.

**Virtual-8086 Mode Exceptions**

#UD If an attempt is made to execute this instruction when the processor is not in SMM.
RSQRTPS—Compute Reciprocals of Square Roots of Packed Single-Precision Floating-Point Values

**Description**

Performs a SIMD computation of the approximate reciprocals of the square roots of the four packed single-precision floating-point values in the source operand (second operand) and stores the packed single-precision floating-point results in the destination operand. The maximum relative error for this approximation is \( \leq 1.5 \times 2^{-12} \). The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. See Figure 10-5 in the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1* for an illustration of a SIMD single-precision floating-point operation.

The RSQRTPS instruction is not affected by the rounding control bits in the MXCSR register. When a source value is a 0.0, an \( \infty \) of the sign of the source value is returned. A denormal source value is treated as a 0.0 (of the same sign). When a source value is a negative value (other than \(-0.0\)), a floating-point indefinite is returned. Underflow results are always flushed to 0.0, with the sign of the operand. When a source value is an SNaN or QNaN, the SNaN converted to a QNaN or the source QNaN is returned.

**Operation**

\[
\begin{align*}
\text{DEST}[31-0] &\leftarrow \text{APPROXIMATE}(1.0/\text{SQRT}(<\text{SRC}[31-0])); \\
\text{DEST}[63-32] &\leftarrow \text{APPROXIMATE}(1.0/\text{SQRT}(<\text{SRC}[63-32])); \\
\text{DEST}[95-64] &\leftarrow \text{APPROXIMATE}(1.0/\text{SQRT}(<\text{SRC}[95-64])); \\
\text{DEST}[127-96] &\leftarrow \text{APPROXIMATE}(1.0/\text{SQRT}(<\text{SRC}[127-96]));
\end{align*}
\]

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
RSQRTSS—Compute Reciprocal of Square Root of Scalar Single-Precision Floating-Point Value

### Description

Computes an approximate reciprocal of the square root of the low single-precision floating-point value in the source operand (second operand) stores the single-precision floating-point result in the destination operand. The maximum relative error for this approximation is \( \leq 1.5 \times 2^{-12} \). The source operand can be an XMM register or a 32-bit memory location. The destination operand is an XMM register. The three high-order doublewords of the destination operand remain unchanged. See Figure 10-6 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1 for an illustration of a scalar single-precision floating-point operation.

The RSQRTPS instruction is not affected by the rounding control bits in the MXCSR register. When a source value is a 0.0, an \( \infty \) of the sign of the source value is returned. A denormal source value is treated as a 0.0 (of the same sign). When a source value is a negative value (other than \(-0.0\)), a floating-point indefinite is returned. Underflow results are always flushed to 0.0, with the sign of the operand. When a source value is an SNaN or QNaN, the SNaN converted to a QNaN or the source QNaN is returned.

### Operation

\[
\text{DEST}[31-0] \leftarrow \text{APPROXIMATE}(1.0/\sqrt{\text{SRC}[31-0]})
\]

* DEST[127-32] remains unchanged *;

### Intel C/C++ Compiler Intrinsic Equivalent

- **#AC(0)** If alignment checking is enabled and an unaligned memory reference is made.
SAHF—Store AH into Flags

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Clocks</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9E</td>
<td>SAHF</td>
<td>2</td>
<td>Loads SF, ZF, AF, PF, and CF from AH into EFLAGS register</td>
</tr>
</tbody>
</table>

**Description**

Loads the SF, ZF, AF, PF, and CF flags of the EFLAGS register with values from the corresponding bits in the AH register (bits 7, 6, 4, 2, and 0, respectively). Bits 1, 3, and 5 of register AH are ignored; the corresponding reserved bits (1, 3, and 5) in the EFLAGS register remain as shown in the “Operation” section below.

**Operation**

EFLAGS(SF:ZF:0:AF:0:PF:1:CF) ← AH;

**Flags Affected**

The SF, ZF, AF, PF, and CF flags are loaded with values from the AH register. Bits 1, 3, and 5 of the EFLAGS register are unaffected, with the values remaining 1, 0, and 0, respectively.

**Exceptions (All Operating Modes)**

None.

NOTE:
* Not the same form of division as IDIV; rounding is toward negative infinity.
SAL/SAR/SHL/SHR—Shift (Continued)

Description

Shifts the bits in the first operand (destination operand) to the left or right by the number of bits specified in the second operand (count operand). Bits shifted beyond the destination operand boundary are first shifted into the CF flag, then discarded. At the end of the shift operation, the CF flag contains the last bit shifted out of the destination operand.

The destination operand can be a register or a memory location. The count operand can be an immediate value or register CL. The count is masked to 5 bits, which limits the count range to 0 to 31. A special opcode encoding is provided for a count of 1.

The shift arithmetic left (SAL) and shift logical left (SHL) instructions perform the same operation; they shift the bits in the destination operand to the left (toward more significant bit locations). For each shift count, the most significant bit of the destination operand is shifted into the CF flag, and the least significant bit is cleared (see Figure 7-7 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1).

The shift arithmetic right (SAR) and shift logical right (SHR) instructions shift the bits of the destination operand to the right (toward less significant bit locations). For each shift count, the least significant bit of the destination operand is shifted into the CF flag, and the most significant bit is either set or cleared depending on the instruction type. The SHR instruction clears the most significant bit (see Figure 7-8 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1); the SAR instruction sets or clears the most significant bit to correspond to the sign (most significant bit) of the original value in the destination operand. In effect, the SAR instruction fills the empty bit position’s shifted value with the sign of the unshifted value (see Figure 7-9 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1).

The SAR and SHR instructions can be used to perform signed or unsigned division, respectively, of the destination operand by powers of 2. For example, using the SAR instruction to shift a signed integer 1 bit to the right divides the value by 2.

Using the SAR instruction to perform a division operation does not produce the same result as the IDIV instruction. The quotient from the IDIV instruction is rounded toward zero, whereas the “quotient” of the SAR instruction is rounded toward negative infinity. This difference is apparent only for negative numbers. For example, when the IDIV instruction is used to divide -9 by 4, the result is -2 with a remainder of -1. If the SAR instruction is used to shift -9 right by two bits, the result is -3 and the “remainder” is +3; however, the SAR instruction stores only the most significant bit of the remainder (in the CF flag).

The OF flag is affected only on 1-bit shifts. For left shifts, the OF flag is cleared to 0 if the most-significant bit of the result is the same as the CF flag (that is, the top two bits of the original operand were the same); otherwise, it is set to 1. For the SAR instruction, the OF flag is cleared for all 1-bit shifts. For the SHR instruction, the OF flag is set to the most-significant bit of the original operand.
INSTRUCTION SET REFERENCE

SAL/SAR/SHL/SHR—Shift (Continued)

IA-32 Architecture Compatibility

The 8086 does not mask the shift count. However, all other IA-32 processors (starting with the Intel 286 processor) do mask the shift count to 5 bits, resulting in a maximum count of 31. This masking is done in all operating modes (including the virtual-8086 mode) to reduce the maximum execution time of the instructions.

Operation

\[
\begin{align*}

\end{align*}
\]
SAL/SAR/SHL/SHR—Shift (Continued)

```
ELSE IF COUNT ← 0
    THEN
        All flags remain unchanged;
    ELSE (* COUNT neither 1 or 0 *)
        OF ← undefined;
    FI;
FI;
```

**Flags Affected**
The CF flag contains the value of the last bit shifted out of the destination operand; it is unde-
fined for SHL and SHR instructions where the count is greater than or equal to the size (in bits) of the destination operand. The OF flag is affected only for 1-bit shifts (see “Description” above); otherwise, it is undefined. The SF, ZF, and PF flags are set according to the result. If the count is 0, the flags are not affected. For a non-zero count, the AF flag is undefined.

**Protected Mode Exceptions**

- **#GP(0)** If the destination is located in a nonwritable segment.
  - If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
    - If the DS, ES, FS, or GS register contains a null segment selector.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
- **#PF(fault-code)** If a page fault occurs.
- **#AC(0)** If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

**Real-Address Mode Exceptions**

- **#GP** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS** If a memory operand effective address is outside the SS segment limit.

**Virtual-8086 Mode Exceptions**

- **#GP(0)** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
- **#PF(fault-code)** If a page fault occurs.
- **#AC(0)** If alignment checking is enabled and an unaligned memory reference is made.

</tbody>
</table>

Description

Adds the source operand (second operand) and the carry (CF) flag, and subtracts the result from the destination operand (first operand). The result of the subtraction is stored in the destination operand. The destination operand can be a register or a memory location; the source operand can be an immediate, a register, or a memory location. (However, two memory operands cannot be used in one instruction.) The state of the CF flag represents a borrow from a previous subtraction.

When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.

The SBB instruction does not distinguish between signed or unsigned operands. Instead, the processor evaluates the result for both data types and sets the OF and CF flags to indicate a borrow in the signed or unsigned result, respectively. The SF flag indicates the sign of the signed result.

The SBB instruction is usually executed as part of a multibyte or multiword subtraction in which a SUB instruction is followed by a SBB instruction.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation

DEST ← DEST − (SRC + CF);
SBB—Integer Subtraction with Borrow (Continued)

Flags Affected
The OF, SF, ZF, AF, PF, and CF flags are set according to the result.

Protected Mode Exceptions

#GP(0) If the destination is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

<td>SCASD</td>
<td>Compare EAX with doubleword at ES:(E)DI and set status flags</td>
</tr>
</tbody>
</table>

Description

Compares the byte, word, or double word specified with the memory operand with the value in the AL, AX, or EAX register, and sets the status flags in the EFLAGS register according to the results. The memory operand address is read from either the ES:EDI or the ES:DI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). The ES segment cannot be overridden with a segment override prefix.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operand form (specified with the SCAS mnemonic) allows the memory operand to be specified explicitly. Here, the memory operand should be a symbol that indicates the size and location of the operand value. The register operand is then automatically selected to match the size of the memory operand (the AL register for byte comparisons, AX for word comparisons, and EAX for doubleword comparisons). This explicit-operand form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the memory operand symbol must specify the correct type (size) of the operand (byte, word, or doubleword), but it does not have to specify the correct location. The location is always specified by the ES:(E)DI registers, which must be loaded correctly before the compare string instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the SCAS instructions. Here also ES:(E)DI is assumed to be the memory operand and the AL, AX, or EAX register is assumed to be the register operand. The size of the two operands is selected with the mnemonic: SCASB (byte comparison), SCASW (word comparison), or SCASD (doubleword comparison).

After the comparison, the (E)DI register is incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)DI register is incremented; if the DF flag is 1, the (E)DI register is decremented.) The (E)DI register is incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.

The SCAS, SCASB, SCASW, and SCASD instructions can be preceded by the REP prefix for block comparisons of ECX bytes, words, or doublewords. More often, however, these instructions will be used in a LOOP construct that takes some action based on the setting of the status flags before the next comparison is made. See “REP/REPE/REPZ/REPNE /REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.
SCAS/SCASB/SCASW/SCASD—Scan String (Continued)

Operation

IF (byte comparison)
    THEN
        temp ← AL – SRC;
        SetStatusFlags(temp);
        THEN IF DF ← 0
            THEN (E)DI ← (E)DI + 1;
            ELSE (E)DI ← (E)DI – 1;
        FI;
        ELSE IF (word comparison)
            THEN
                temp ← AX – SRC;
                SetStatusFlags(temp)
                THEN IF DF ← 0
                    THEN (E)DI ← (E)DI + 2;
                    ELSE (E)DI ← (E)DI – 2;
                FI;
                ELSE (* doubleword comparison *)
                    temp ← EAX – SRC;
                    SetStatusFlags(temp)
                    THEN IF DF ← 0
                        THEN (E)DI ← (E)DI + 4;
                        ELSE (E)DI ← (E)DI – 4;
                    FI;
                FI;
            FI;
    FI;

Flags Affected

The OF, SF, ZF, AF, PF, and CF flags are set according to the temporary result of the comparison.

Protected Mode Exceptions

#GP(0) If a memory operand effective address is outside the limit of the ES segment.
    If the ES register contains a null segment selector.
    If an illegal memory operand effective address in the ES segment is given.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
SCAS/SCASB/SCASW/SCASD—Scan String (Continued)

Real-Address Mode Exceptions

#GP  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS  If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0)  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0)  If a memory operand effective address is outside the SS segment limit.

#PF(fault-code)  If a page fault occurs.

#AC(0)  If alignment checking is enabled and an unaligned memory reference is made.

Description

Set the destination operand to 0 or 1 depending on the settings of the status flags (CF, SF, OF, ZF, and PF) in the EFLAGS register. The destination operand points to a byte register or a byte in memory. The condition code suffix (cc) indicates the condition being tested for.

The terms “above” and “below” are associated with the CF flag and refer to the relationship between two unsigned integer values. The terms “greater” and “less” are associated with the SF and OF flags and refer to the relationship between two signed integer values.
SETcc—Set Byte on Condition (Continued)

Many of the SETcc instruction opcodes have alternate mnemonics. For example, SETG (set byte if greater) and SETNLE (set if not less or equal) have the same opcode and test for the same condition: ZF equals 0 and SF equals OF. These alternate mnemonics are provided to make code more intelligible. Appendix B, EFLAGS Condition Codes, in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1, shows the alternate mnemonics for various test conditions.

Some languages represent a logical one as an integer with all bits set. This representation can be obtained by choosing the logically opposite condition for the SETcc instruction, then decrementing the result. For example, to test for overflow, use the SETNO instruction, then decrement the result.

**Operation**

IF condition
    THEN DEST ← 1
    ELSE DEST ← 0;

**Virtual-8086 Mode Exceptions**

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
SFENCE—Store Fence

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F AE /7</td>
<td>SFENCE</td>
<td>Serializes store operations.</td>
</tr>
</tbody>
</table>

Description

Performs a serializing operation on all store-to-memory instructions that were issued prior the SFENCE instruction. This serializing operation guarantees that every store instruction that precedes in program order the SFENCE instruction is globally visible before any store instruction that follows the SFENCE instruction is globally visible. The SFENCE instruction is ordered with respect to store instructions, other SFENCE instructions, any MFENCE instructions, and any serializing instructions (such as the CPUID instruction). It is not ordered with respect to load instructions or the LFENCE instruction.

Weakly ordered memory types can be used to achieve higher processor performance through such techniques as out-of-order issue, write-combining, and write-collapsing. The degree to which a consumer of data recognizes or knows that the data is weakly ordered varies among applications and may be unknown to the producer of this data. The SFENCE instruction provides a performance-efficient way of insuring store ordering between routines that produce weakly-ordered results and routines that consume this data.

Operation

Wait_On_Following_Stores_Until(preceding_stores_globally_visible);

Intel C/C++ Compiler Intrinsic Equivalent

SGDT/SIDT—Store Global/Interrupt Descriptor Table Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 01 /0</td>
<td>SGDT m</td>
<td>Store GDTR to m</td>
</tr>
<tr>
<td>0F 01 /1</td>
<td>SIDT m</td>
<td>Store IDTR to m</td>
</tr>
</tbody>
</table>

**Description**

Stores the contents of the global descriptor table register (GDTR) or the interrupt descriptor table register (IDTR) in the destination operand. The destination operand specifies a 6-byte memory location. If the operand-size attribute is 32 bits, the 16-bit limit field of the register is stored in the lower 2 bytes of the memory location and the 32-bit base address is stored in the upper 4 bytes. If the operand-size attribute is 16 bits, the limit is stored in the lower 2 bytes and the 24-bit base address is stored in the third, fourth, and fifth byte, with the sixth byte filled with 0s.

The SGDT and SIDT instructions are only useful in operating-system software; however, they can be used in application programs without causing an exception to be generated.

See “LGDT/LIDT—Load Global/Interrupt Descriptor Table Register” in this chapter for information on loading the GDTR and IDTR.

**IA-32 Architecture Compatibility**

The 16-bit forms of the SGDT and SIDT instructions are compatible with the Intel 286 processor, if the upper 8 bits are not referenced. The Intel 286 processor fills these bits with 1s; the Pentium Pro, Pentium, Intel486, and Intel386 processors fill these bits with 0s.

**Operation**

<tr>
<td>0F A5</td>
<td>SHLD r/m32, r32, CL</td>
<td>Shift r/m32 to left CL places while shifting bits from r32 in from the right</td>
</tr>
</tbody>
</table>

**Description**

Shifts the first operand (destination operand) to the left the number of bits specified by the third operand (count operand). The second operand (source operand) provides bits to shift in from the right (starting with bit 0 of the destination operand). The destination operand can be a register or a memory location; the source operand is a register. The count operand is an unsigned integer that can be an immediate byte or the contents of the CL register. Only bits 0 through 4 of the count are used, which masks the count to a value between 0 and 31. If the count is greater than the operand size, the result in the destination operand is undefined.

If the count is 1 or greater, the CF flag is filled with the last bit shifted out of the destination operand. For a 1-bit shift, the OF flag is set if a sign change occurred; otherwise, it is cleared. If the count operand is 0, the flags are not affected.

The SHLD instruction is useful for multi-precision shifts of 64 bits or more.

**Operation**

```
COUNT ← COUNT MOD 32;
SIZE ← OperandSize
IF COUNT = 0
    THEN
        no operation
    ELSE
        IF COUNT > SIZE
            THEN (* Bad parameters *)
                DEST is undefined;
                CF, OF, SF, ZF, AF, PF are undefined;
            ELSE (* Perform the shift *)
                CF ← BIT[DEST, SIZE – COUNT];
                (* Last bit shifted out on exit *)
                FOR i ← SIZE – 1 DOWNTO COUNT
                    DO
                        Bit(DEST, i) ← Bit(DEST, i – COUNT);  
                        OD;
```

SHLD—Double Precision Shift Left (Continued)

FOR i ← COUNT – 1 DOWNTO 0
  DO
    BIT[DEST, i] ← BIT[SRC, i – COUNT + SIZE];
  OD;
FI;
FI;

Flags Affected
If the count is 1 or greater, the CF flag is filled with the last bit shifted out of the destination operand and the SF, ZF, and PF flags are set according to the value of the result. For a 1-bit shift, the OF flag is set if a sign change occurred; otherwise, it is cleared. For shifts greater than 1 bit, the OF flag is undefined. If a shift occurs, the AF flag is undefined. If the count operand is 0, the flags are not affected. If the count is greater than the operand size, the flags are undefined.

Protected Mode Exceptions
#GP(0) If the destination is located in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

</tr>
<tr>
<td>0F AD</td>
<td>SHRD r/m32, r32, CL</td>
<td>Shift r/m32 to right CL places while shifting bits from r32 in from the left</td>
</tr>
</tbody>
</table>

### Description

Shifts the first operand (destination operand) to the right the number of bits specified by the third operand (count operand). The second operand (source operand) provides bits to shift in from the left (starting with the most significant bit of the destination operand). The destination operand can be a register or a memory location; the source operand is a register. The count operand is an unsigned integer that can be an immediate byte or the contents of the CL register. Only bits 0 through 4 of the count are used, which masks the count to a value between 0 and 31. If the count is greater than the operand size, the result in the destination operand is undefined.

If the count is 1 or greater, the CF flag is filled with the last bit shifted out of the destination operand. For a 1-bit shift, the OF flag is set if a sign change occurred; otherwise, it is cleared. If the count operand is 0, the flags are not affected.

The SHRD instruction is useful for multiprecision shifts of 64 bits or more.

### Operation

COUNT ← COUNT MOD 32;  
SIZE ← OperandSize  
IF COUNT = 0  
   THEN  
      no operation  
   ELSE  
      IF COUNT > SIZE  
         THEN (* Bad parameters *)  
            DEST is undefined;  
            CF, OF, SF, ZF, AF, PF are undefined;  
         ELSE (* Perform the shift *)  
            CF ← BIT[DEST, COUNT − 1]; (* last bit shifted out on exit *)  
            FOR i ← 0 TO SIZE − 1 − COUNT  
               DO  
                  BIT[DEST, i] ← BIT[DEST, i + COUNT];  
               OD;  
      OD;
SHRD—Double Precision Shift Right (Continued)

FOR i ← SIZE – COUNT TO SIZE – 1
   DO
      BIT[DEST, i] ← BIT[SRC, i + COUNT – SIZE];
   OD;
FI;
FI;

Flags Affected
If the count is 1 or greater, the CF flag is filled with the last bit shifted out of the destination operand and the SF, ZF, and PF flags are set according to the value of the result. For a 1-bit shift, the OF flag is set if a sign change occurred; otherwise, it is cleared. For shifts greater than 1 bit, the OF flag is undefined. If a shift occurs, the AF flag is undefined. If the count operand is 0, the flags are not affected. If the count is greater than the operand size, the flags are undefined.

Protected Mode Exceptions
#GP(0) If the destination is located in a nonwritable segment.
   If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
   If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
SHUFPD—Shuffle Packed Double-Precision Floating-Point Values

Description
Moves either of the two packed double-precision floating-point values from destination operand (first operand) into the low quadword of the destination operand; moves either of the two packed double-precision floating-point values from the source operand into to the high quadword of the destination operand (see Figure 3-16). The select operand (third operand) determines which values are moved to the destination operand.

![SHUFPD Shuffle Operation Diagram](image)

The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The select operand is an 8-bit immediate: bit 0 selects which value is moved from the destination operand to the result (where 0 selects the low quadword and 1 selects the high quadword) and bit 1 selects which value is moved from the source operand to the result. Bits 3 through 7 of the shuffle operand are reserved.

Operation
IF SELECT[0] == 0
   THEN DEST[63-0] ← DEST[63-0];
   ELSE DEST[63-0] ← DEST[127-64]; FI;
IF SELECT[1] == 0
   THEN DEST[127-64] ← SRC[63-0];
   ELSE DEST[127-64] ← SRC[127-64]; FI;

</tr>
</tbody>
</table>

Description

Moves two of the four packed single-precision floating-point values from the destination operand (first operand) into the low quadword of the destination operand; moves two of the four packed single-precision floating-point values from the source operand (second operand) into the high quadword of the destination operand (see Figure 3-17). The select operand (third operand) determines which values are moved to the destination operand.

![Diagram](image)

Figure 3-17. SHUFPS Shuffle Operation

The source operand can be an XXM register or a 128-bit memory location. The destination operand is an XMM register. The select operand is an 8-bit immediate: bits 0 and 1 select the value to be moved from the destination operand the low doubleword of the result, bits 2 and 3 select the value to be moved from the destination operand the second doubleword of the result, bits 4 and 5 select the value to be moved from the source operand the third doubleword of the result, and bits 6 and 7 select the value to be moved from the source operand the high doubleword of the result.

Operation

If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
SIDT—Store Interrupt Descriptor Table Register

See entry for SGDT/SIDT—Store Global/Interrupt Descriptor Table Register.
SLDT—Store Local Descriptor Table Register

Stores the segment selector from the local descriptor table register (LDTR) in the destination operand. The destination operand can be a general-purpose register or a memory location. The segment selector stored with this instruction points to the segment descriptor (located in the GDT) for the current LDT. This instruction can only be executed in protected mode.

When the destination operand is a 32-bit register, the 16-bit segment selector is copied into the lower-order 16 bits of the register. The high-order 16 bits of the register are cleared to 0s for the Pentium Pro processor and are undefined for Pentium, Intel486, and Intel386 processors. When the destination operand is a memory location, the segment selector is written to memory as a 16-bit quantity, regardless of the operand size.

The SLDT instruction is only useful in operating-system software; however, it can be used in application programs.

Operation

DEST ← LDTR(SegmentSelector);

Flags Affected

None.

Protected Mode Exceptions

- #GP(0) If the destination is located in a nonwritable segment.
  - If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  - If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

- #SS(0) If a memory operand effective address is outside the SS segment limit.

- #PF(fault-code) If a page fault occurs.

- #AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
SLDT—Store Local Descriptor Table Register (Continued)

Real-Address Mode Exceptions

#UD The SLDT instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD The SLDT instruction is not recognized in virtual-8086 mode.
**SMSW—Store Machine Status Word**

Stores the machine status word (bits 0 through 15 of control register CR0) into the destination operand. The destination operand can be a 16-bit general-purpose register or a memory location.

When the destination operand is a 32-bit register, the low-order 16 bits of register CR0 are copied into the low-order 16 bits of the register and the upper 16 bits of the register are undefined. When the destination operand is a memory location, the low-order 16 bits of register CR0 are written to memory as a 16-bit quantity, regardless of the operand size.

The SMSW instruction is only useful in operating-system software; however, it is not a privileged instruction and can be used in application programs.

This instruction is provided for compatibility with the Intel 286 processor. Programs and procedures intended to run on the Pentium Pro, Pentium, Intel486, and Intel386 processors should use the MOV (control registers) instruction to load the machine status word.

### Operation

\[ \text{DEST} \leftarrow \text{CR0}[15:0]; \ (* \text{Machine status word} *); \]

### Flags Affected

None.

### Protected Mode Exceptions

- **#GP(0)**
  If the destination is located in a nonwritable segment.
  
  If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  
  If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
STC—Set Carry Flag

Description
Sets the CF flag in the EFLAGS register.

Operation
CF ← 1;

Flags Affected
The CF flag is set. The OF, ZF, SF, AF, and PF flags are unaffected.

Exceptions (All Operating Modes)
None.

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F9</td>
<td>STC</td>
<td>Set CF flag</td>

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FD</td>
<td>STD</td>
<td>Set DF flag</td>
</tr>
</tbody>
</table>

**Description**
Sets the DF flag in the EFLAGS register. When the DF flag is set to 1, string operations decrement the index registers (ESI and/or EDI).

**Operation**
DF ← 1;

**Flags Affected**
The DF flag is set. The CF, OF, ZF, SF, AF, and PF flags are unaffected.

**Operation**
DF ← 1;

**Exceptions (All Operating Modes)**
None.
STI—Set Interrupt Flag

**Description**

Sets the interrupt flag (IF) in the EFLAGS register. After the IF flag is set, the processor begins responding to external, maskable interrupts after the next instruction is executed. The delayed effect of this instruction is provided to allow interrupts to be enabled just before returning from a procedure (or subroutine). For instance, if an STI instruction is followed by a RET instruction, the RET instruction is allowed to execute before external interrupts are recognized. This behavior allows external interrupts to be disabled at the beginning of a procedure and enabled again at the end of the procedure. If the STI instruction is followed by a CLI instruction (which clears the IF flag), the effect of the STI instruction is negated.

The IF flag and the STI and CLI instructions have no affect on the generation of exceptions and NMI interrupts.

The following decision table indicates the action of the STI instruction (bottom of the table) depending on the processor’s mode of operation and the CPL and IOPL of the currently running program or procedure (top of the table).

<table>
<thead>
<tr>

</tbody>
</table>

**NOTES:**

X Don’t care.
N Action in Column 1 not taken.
Y Action in Column 1 taken.

---

1. Note that in a sequence of instructions that individually delay interrupts past the following instruction, only the first instruction in the sequence is guaranteed to delay the interrupt, but subsequent interrupt-delaying instructions may not delay the interrupt. Thus, in the following instruction sequence:

   STI
   MOV SS, AX
   MOV ESP, EBP

   interrupts may be recognized before MOV ESP, EBP executes, even though MOV SS, AX normally delays interrupts for one instruction.
STI—Set Interrupt Flag (Continued)

Operation
IF PE=0 (* Executing in real-address mode *)
    THEN
        IF ← 1; (* Set Interrupt Flag *)
        ELSE (* Executing in protected mode or virtual-8086 mode *)
            IF VM=0 (* Executing in protected mode *)
                THEN
                    IF IOPL ← 3
                        THEN

                FI;
        FI;
Flags Affected
The IF flag is set to 1.

Protected Mode Exceptions
#GP(0) If the CPL is greater (has less privilege) than the IOPL of the current program or procedure.

Real-Address Mode Exceptions
None.

Virtual-8086 Mode Exceptions
#GP(0) If the CPL is greater (has less privilege) than the IOPL of the current program or procedure.
STMXCSR—Store MXCSR Register State

Description
Stores the contents of the MXCSR control and status register to the destination operand. The destination operand is a 32-bit memory location. The reserved bits in the MXCSR register are stored as 0s.

Operation
m32 ← MXCSR;

Intel C/C++ Compiler Intrinsic Equivalent
_mm_getcsr(void)

Exceptions
None.

Numeric Exceptions
None.

Protected Mode Exceptions
- #GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS, or GS segments.
- #SS(0) For an illegal address in the SS segment.
- #PF(fault-code) For a page fault.
- #UD If CR0.EM = 1.
- #NM If TS bit in CR0 is set.
- #AC For unaligned memory reference. To enable #AC exceptions, three conditions must be true(CR0.AM is set; EFLAGS.AC is set; current CPL is 3).
- #UD If CR4.OSFXSR(bit 9) = 0.
- #UD If CPUID.XMM(EDX bit 25) = 0.
STMXCSR—Store MXCSR Register State (Continued)

Real Address Mode Exceptions

Interrupt 13  If any part of the operand would lie outside of the effective address space from 0 to 0FFFFH.
#UD  If CR0.EM = 1.
#NM  If TS bit in CR0 is set.
#UD  If CR4.OSFXSR(bit 9) = 0.
#UD  If CPUID.XMM(EDX bit 25) = 0.

Virtual 8086 Mode Exceptions

Same exceptions as in Real Address Mode.

#PF(fault-code)  For a page fault.
#AC  For unaligned memory reference.

<td>AB</td>
<td>STOSW</td>
<td>Store AX at address ES:(E)DI</td>
</tr>
<tr>
<td>AB</td>
<td>STOSD</td>
<td>Store EAX at address ES:(E)DI</td>
</tr>
</tbody>
</table>

Description

Stores a byte, word, or doubleword from the AL, AX, or EAX register, respectively, into the destination operand. The destination operand is a memory location, the address of which is read from either the ES:EDI or the ES:DI registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). The ES segment cannot be overridden with a segment override prefix.

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operands” form and the “no-operands” form. The explicit-operands form (specified with the STOS mnemonic) allows the destination operand to be specified explicitly. Here, the destination operand should be a symbol that indicates the size and location of the destination value. The source operand is then automatically selected to match the size of the destination operand (the AL register for byte operands, AX for word operands, and EAX for doubleword operands). This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the destination operand symbol must specify the correct type (size) of the operand (byte, word, or doubleword), but it does not have to specify the correct location. The location is always specified by the ES:(E)DI registers, which must be loaded correctly before the store string instruction is executed.

The no-operands form provides “short forms” of the byte, word, and doubleword versions of the STOS instructions. Here also ES:(E)DI is assumed to be the destination operand and the AL, AX, or EAX register is assumed to be the source operand. The size of the destination and source operands is selected with the mnemonic: STOSB (byte read from register AL), STOSW (word from AX), or STOSD (doubleword from EAX).

After the byte, word, or doubleword is transferred from the AL, AX, or EAX register to the memory location, the (E)DI register is incremented or decremented automatically according to the setting of the DF flag in the EFLAGS register. (If the DF flag is 0, the (E)DI register is incremented; if the DF flag is 1, the (E)DI register is decremented.) The (E)DI register is incremented or decremented by 1 for byte operations, by 2 for word operations, or by 4 for doubleword operations.
STOS/STOSB/STOSW/STOSD—Store String (Continued)

The STOS, STOSB, STOSW, and STOSD instructions can be preceded by the REP prefix for block loads of ECX bytes, words, or doublewords. More often, however, these instructions are used within a LOOP construct because data needs to be moved into the AL, AX, or EAX register before it can be stored. See “REP/REPE/REPZ/REPNE/REPNZ—Repeat String Operation Prefix” in this chapter for a description of the REP prefix.

Operation

IF (byte store)
    THEN
        DEST ← AL;
        THEN IF DF ← 0
            THEN (E)DI ← (E)DI + 1;
            ELSE (E)DI ← (E)DI − 1;
        FI;
    ELSE IF (word store)
        THEN
            DEST ← AX;
            THEN IF DF ← 0
                THEN (E)DI ← (E)DI + 2;
                ELSE (E)DI ← (E)DI − 2;
            FI;
        ELSE (* doubleword store *)
            DEST ← EAX;
            THEN IF DF ← 0
                THEN (E)DI ← (E)DI + 4;
                ELSE (E)DI ← (E)DI − 4;
            FI;
    FI;
FI;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If the destination is located in a nonwritable segment.
    If a memory operand effective address is outside the limit of the ES segment.
    If the ES register contains a null segment selector.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the ES segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the ES segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

STR—Store Task Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 00 /1</td>
<td>STR r/m16</td>
<td>Stores segment selector from TR in r/m16</td>
</tr>
</tbody>
</table>

**Description**
Stores the segment selector from the task register (TR) in the destination operand. The destination operand can be a general-purpose register or a memory location. The segment selector stored with this instruction points to the task state segment (TSS) for the currently running task.

When the destination operand is a 32-bit register, the 16-bit segment selector is copied into the lower 16 bits of the register and the upper 16 bits of the register are cleared to 0s. When the destination operand is a memory location, the segment selector is written to memory as a 16-bit quantity, regardless of operand size.

The STR instruction is useful only in operating-system software. It can only be executed in protected mode.

**Operation**

DEST ← TR(SegmentSelector);

**Flags Affected**
None.

**Protected Mode Exceptions**

- **#GP(0)**: If the destination is a memory operand that is located in a nonwritable segment or if the effective address is outside the CS, DS, ES, FS, or GS segment limit.
  
  If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.

- **#SS(0)**: If a memory operand effective address is outside the SS segment limit.

- **#PF(fault-code)**: If a page fault occurs.

- **#AC(0)**: If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

**Real-Address Mode Exceptions**

- **#UD**: The STR instruction is not recognized in real-address mode.
Virtual-8086 Mode Exceptions

#UD        The STR instruction is not recognized in virtual-8086 mode.
SUB—Subtract

Description
Subtracts the second operand (source operand) from the first operand (destination operand) and stores the result in the destination operand. The destination operand can be a register or a memory location; the source operand can be an immediate, register, or memory location. (However, two memory operands cannot be used in one instruction.) When an immediate value is used as an operand, it is sign-extended to the length of the destination operand format.

The SUB instruction performs integer subtraction. It evaluates the result for both signed and unsigned integer operands and sets the OF and CF flags to indicate a borrow in the signed or unsigned result, respectively. The SF flag indicates the sign of the signed result.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

Operation
DEST ← DEST – SRC;

Flags Affected
The OF, SF, ZF, AF, PF, and CF flags are set according to the result.

INSTRUCTION SET REFERENCE

SYSENTER—Fast System Call

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 34</td>
<td>SYSENTER</td>
<td>Fast call to privilege level 0 system procedures</td>
</tr>
</tbody>
</table>

**Description**

Executes a fast call to a level 0 system procedure or routine. This instruction is a companion instruction to the SYSEXIT instruction. The SYSENTER instruction is optimized to provide the maximum performance for system calls from user code running at privilege level 3 to operating system or executive procedures running at privilege level 0.

Prior to executing the SYSENTER instruction, software must specify the privilege level 0 code segment and code entry point, and the privilege level 0 stack segment and stack pointer by writing values into the following MSRs:

- **SYSENTER_CS_MSR**—Contains the 32-bit segment selector for the privilege level 0 code segment. (This value is also used to compute the segment selector of the privilege level 0 stack segment.)
- **SYSENTER_EIP_MSR**—Contains the 32-bit offset into the privilege level 0 code segment to the first instruction of the selected operating procedure or routine.
- **SYSENTER_ESP_MSR**—Contains the 32-bit stack pointer for the privilege level 0 stack.

These MSRs can be read from and written to using the RDMSR and WRMSR instructions. The register addresses are listed in Table 3-14. These addresses are defined to remain fixed for future IA-32 processors.

**Table 3-14. MSRs Used By the SYSENTER and SYSEXIT Instructions**

<table>
<thead>
<tr>
<th>MSR</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSENTER_CS_MSR</td>
<td>174H</td>
</tr>
<tr>
<td>SYSENTER_ESP_MSR</td>
<td>175H</td>
</tr>
<tr>
<td>SYSENTER_EIP_MSR</td>
<td>176H</td>
</tr>
</tbody>
</table>

When the SYSENTER instruction is executed, the processor does the following:

1. Loads the segment selector from the SYSENTER_CS_MSR into the CS register.
2. Loads the instruction pointer from the SYSENTER_EIP_MSR into the EIP register.
3. Adds 8 to the value in SYSENTER_CS_MSR and loads it into the SS register.
4. Loads the stack pointer from the SYSENTER_ESP_MSR into the ESP register.
5. Switches to privilege level 0.
6. Clears the VM flag in the EFLAGS register, if the flag is set.
7. Begins executing the selected system procedure.
SYSENTER—Fast System Call (Continued)

The processor does not save a return IP or other state information for the calling procedure.

The SYSENTER instruction always transfers program control to a protected-mode code segment with a DPL of 0. The instruction requires that the following conditions are met by the operating system:

- The segment descriptor for the selected system code segment selects a flat, 32-bit code segment of up to 4 GBytes, with execute, read, accessed, and non-conforming permissions.
- The segment descriptor for selected system stack segment selects a flat 32-bit stack segment of up to 4 GBytes, with read, write, accessed, and expand-up permissions.

The SYSENTER can be invoked from all operating modes except real-address mode.

The SYSENTER and SYSEXIT instructions are companion instructions, but they do not constitute a call/return pair. When executing a SYSENTER instruction, the processor does not save state information for the user code, and neither the SYSENTER nor the SYSEXIT instruction supports passing parameters on the stack.

To use the SYSENTER and SYSEXIT instructions as companion instructions for transitions between privilege level 3 code and privilege level 0 operating system procedures, the following conventions must be followed:

- The segment descriptors for the privilege level 0 code and stack segments and for the privilege level 3 code and stack segments must be contiguous in the global descriptor table. This convention allows the processor to compute the segment selectors from the value entered in the SYSENTER_CS_MSR MSR.
- The fast system call “stub” routines executed by user code (typically in shared libraries or DLLs) must save the required return IP and processor state information if a return to the calling procedure is required. Likewise, the operating system or executive procedures called with SYSENTER instructions must have access to and use this saved return and state information when returning to the user code.

The SYSENTER and SYSEXIT instructions were introduced into the IA-32 architecture in the Pentium II processor. The availability of these instructions on a processor is indicated with the SYSENTER/SYSEXIT present (SEP) feature flag returned to the EDX register by the CPUID instruction. An operating system that qualifies the SEP flag must also qualify the processor family and model to ensure that the SYSENTER/SYSEXIT instructions are actually present. For example:

```plaintext
IF (CPUID SEP bit is set)
  THEN IF (Family == 6) AND (Model < 3) AND (Stepping < 3)
    THEN SYSENTER/SYSEXIT_Not_Supported
    FI;
  ELSE SYSENTER/SYSEXIT_Supported
FI;
```
SYSENTER—Fast System Call (Continued)

When the CPUID instruction is executed on the Pentium Pro processor (model 1), the processor returns a the SEP flag as set, but does not support the SYSENTER/SYSEXIT instructions.

SYSEXIT—Fast Return from Fast System Call

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 35</td>
<td>SYSEXIT</td>
<td>Fast return to privilege level 3 user code.</td>
</tr>
</tbody>
</table>

**Description**

Executes a fast return to privilege level 3 user code. This instruction is a companion instruction to the SYSENTER instruction. The SYSEXIT instruction is optimized to provide the maximum performance for returns from system procedures executing at protections levels 0 to user procedures executing at protection level 3. This instruction must be executed from code executing at privilege level 0.

Prior to executing the SYSEXIT instruction, software must specify the privilege level 3 code segment and code entry point, and the privilege level 3 stack segment and stack pointer by writing values into the following MSR and general-purpose registers:

- **SYSENTER_CS_MSR**—Contains the 32-bit segment selector for the privilege level 0 code segment in which the processor is currently executing. (This value is used to compute the segment selectors for the privilege level 3 code and stack segments.)
- **EDX**—Contains the 32-bit offset into the privilege level 3 code segment to the first instruction to be executed in the user code.
- **ECX**—Contains the 32-bit stack pointer for the privilege level 3 stack.

The SYSENTER_CS_MSR MSR can be read from and written to using the RDMSR and WRMSR instructions. The register address is listed in Table 3-14. This address is defined to remain fixed for future IA-32 processors.

When the SYSEXIT instruction is executed, the processor does the following:

1. Adds 16 to the value in SYSENTER_CS_MSR and loads the sum into the CS selector register.
2. Loads the instruction pointer from the EDX register into the EIP register.
3. Adds 24 to the value in SYSENTER_CS_MSR and loads the sum into the SS selector register.
4. Loads the stack pointer from the ECX register into the ESP register.
5. Switches to privilege level 3.
6. Begins executing the user code at the EIP address.

See “SYSENTER—Fast System Call” for information about using the SYSENTER and SYSEXIT instructions as companion call and return instructions.
SYSEXIT—Fast Return from Fast System Call (Continued)

The SYSEXIT instruction always transfers program control to a protected-mode code segment with a DPL of 3. The instruction requires that the following conditions are met by the operating system:

- The segment descriptor for the selected user code segment selects a flat, 32-bit code segment of up to 4 GBytes, with execute, read, accessed, and non-conforming permissions.
- The segment descriptor for selected user stack segment selects a flat, 32-bit stack segment of up to 4 GBytes, with expand-up, read, write, and accessed permissions.

The SYSENTER can be invoked from all operating modes except real-address mode.

The SYSENTER and SYSEXIT instructions were introduced into the IA-32 architecture in the Pentium II processor. The availability of these instructions on a processor is indicated with the SYSENTER/SYSEXIT present (SEP) feature flag returned to the EDX register by the CPUID instruction. An operating system that qualifies the SEP flag must also qualify the processor family and model to ensure that the SYSENTER/SYSEXIT instructions are actually present. For example:

```plaintext
IF (CPUID SEP bit is set)
  THEN IF (Family == 6) AND (Model < 3) AND (Stepping < 3)
    THEN
      SYSENTER/SYSEXIT_Not_Supported
      FI;
    ELSE SYSENTER/SYSEXIT_Supported
    FI;
ELSE SYSENTER/SYSEXIT_Supported
FI;
```

When the CPUID instruction is executed on the Pentium Pro processor (model 1), the processor returns a the SEP flag as set, but does not support the SYSENTER/SYSEXIT instructions.

**Operation**

```
IF SYSENTER_CS_MSR = 0 THEN #GP(0); FI;
IF CR0.PE = 0 THEN #GP(0); FI;
IF CPL ≠ 0 THEN #GP(0)
CS.SEL ← (SYSENTER_CS_MSR + 16) (* Segment selector for return CS *)
(" Set rest of CS to a fixed value ")
CS.BASE ← 0 (* Flat segment *)
CS.LIMIT ← FFFFH (* 4 GByte limit *)
CS.ARbyte.G ← 1 (* 4 KByte granularity *)
CS.ARbyte.S ← 1
CS.ARbyte.TYPE ← 1011B (* Execute, Read, Non-Conforming Code *)
CS.ARbyte.D ← 1 (* 32-bit code segment*)
CS.ARbyte.DPL ← 3
CS.ARbyte.RPL ← 3
CS.ARbyte.P ← 1
SS.SEL ← (SYSENTER_CS_MSR + 24) (* Segment selector for return SS *)
```
SYSEXIT—Fast Return from Fast System Call (Continued)

( * Set rest of SS to a fixed value *)

SS.BASE ← 0 (* Flat segment *)
SS.LIMIT ← FFFFH (* 4 GByte limit *)
SS.ARbyte.G ← 1 (* 4 KByte granularity *)

SS.ARbyte.TYPE ← 0011B (* Expand Up, Read/Write, Data *)
SS.ARbyte.D ← 1 (* 32-bit stack segment *)
SS.ARbyte.DPL ← 3
SS.ARbyte.RPL ← 3
SS.ARbyte.P ← 1

ESP ← ECX
EIP ← EDX

Flags Affected
None.

Protected Mode Exceptions
#GP(0) If SYSENTER_CS_MSR contains zero.

Real-Address Mode Exceptions
#GP(0) If protected mode is not enabled.

Virtual-8086 Mode Exceptions
#GP(0) If SYSENTER_CS_MSR contains zero.
TEST—Logical Compare

Computes the bit-wise logical AND of first operand (source 1 operand) and the second operand (source 2 operand) and sets the SF, ZF, and PF status flags according to the result. The result is then discarded.

**Operation**

\[
\begin{align*}
\text{TEMP} & \leftarrow \text{SRC1 AND SRC2;} \\
\text{SF} & \leftarrow \text{MSB(TEMP);} \\
\text{IF TEMP} & \leftarrow 0 \\
& \quad \text{THEN ZF} \leftarrow 1; \\
& \quad \text{ELSE ZF} \leftarrow 0; \\
\text{FI;} \\
\text{PF} & \leftarrow \text{BitwiseXNOR(TEMP[0:7]);} \\
\text{CF} & \leftarrow 0; \\
\text{OF} & \leftarrow 0; \\
& \quad \text{(*AF is Undefined*)}
\end{align*}
\]

**Flags Affected**

The OF and CF flags are cleared to 0. The SF, ZF, and PF flags are set according to the result (see the “Operation” section above). The state of the AF flag is undefined.

**Protected Mode Exceptions**

- **#GP(0)** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
  If the DS, ES, FS, or GS register contains a null segment selector.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
- **#PF(fault-code)** If a page fault occurs.
TEST—Logical Compare (Continued)

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
Unordered Compare Scalar Double-Precision Floating-Point Values and Set EFLAGS

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>66 0F 2E /r</td>
<td>UCOMISD xmm1, xmm2/m64</td>
<td>Compares (unordered) the low double-precision floating-point values in xmm1 and xmm2/m64 and set the EFLAGS accordingly.</td>
</tr>
</tbody>
</table>

Description

Performs an unordered compare of the double-precision floating-point values in the low quad-words of source operand 1 (first operand) and source operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Source operand 1 is an XMM register; source operand 2 can be an XMM register or a 64 bit memory location.

The UCOMISD instruction differs from the COMISD instruction in that it signals a SIMD floating-point invalid operation exception (#I) only when a source operand is an SNaN. The COMISD instruction signals an invalid operation exception if a source operand is either a QNaN or an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Operation

RESULT ← UnorderedCompare(SRC1[63-0] <> SRC2[63-0]) {  
  * Set EFLAGS *CASE (RESULT) OF  
    UNORDERED: ZF,PF,CF ← 111;  
    GREATER_THAN: ZF,PF,CF ← 000;  
    LESS_THAN: ZF,PF,CF ← 001;  
    EQUAL: ZF,PF,CF ← 100;  
  ESAC;  
  OF,AF,SF ← 0;  
}

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
UCOMISS—Unordered Compare Scalar Single-Precision Floating-Point Values and Set EFLAGS

Description
Performs and unordered compare of the single-precision floating-point values in the low double-words of the source operand 1 (first operand) and the source operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). In The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Source operand 1 is an XMM register; source operand 2 can be an XMM register or a 32 bit memory location.

The UCOMISS instruction differs from the COMISS instruction in that it signals a SIMD floating-point invalid operation exception (#I) only when a source operand is an SNaN. The COMISS instruction signals an invalid operation exception if a source operand is either a QNaN or an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Operation
RESULT ← UnorderedCompare(SRC1[63-0] <> SRC2[63-0])

UNPCKHPS—Unpack and Interleave High Packed Single-Precision Floating-Point Values (Continued)

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
UNPCKLPD—Unpack and Interleave Low Packed Double-Precision Floating-Point Values

Description
Performs an interleaved unpack of the low double-precision floating-point values from the source operand (second operand) and the destination operand (first operand). See Figure 3-20. The source operand can be an XMM register or a 128-bit memory location; the destination operand is an XMM register.

When unpacking from a memory operand, an implementation may fetch only the appropriate 64 bits; however, alignment to 16-byte boundary and normal segment checking will still be enforced.

Operation
DEST[63-0] ← DEST[63-0];
DEST[127-64] ← SRC[63-0];

Intel C/C++ Compiler Intrinsic Equivalent
UNPCKHPD __m128d __mm_unpacklo_pd(__m128d a, __m128d b)
UNPCKLPD—Unpack and Interleave Low Packed Double-Precision Floating-Point Values (Continued)

SIMD Floating-Point Exceptions
None.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
If memory operand is not aligned on a 16-byte boundary, regardless of segment.

#SS(0) For an illegal address in the SS segment.

#PF(fault-code) For a page fault.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE2 is 0.

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.

Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
If EM in CR0 is set.
If OSFXSR in CR4 is 0.
If CPUID feature flag SSE2 is 0.

VERR, VERW—Verify a Segment for Reading or Writing

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 00 /4</td>
<td>VERR r/m16</td>
<td>Set ZF=1 if segment specified with r/m16 can be read</td>
</tr>
<tr>
<td>0F 00 /5</td>
<td>VERW r/m16</td>
<td>Set ZF=1 if segment specified with r/m16 can be written</td>
</tr>
</tbody>
</table>

**Description**

Verifies whether the code or data segment specified with the source operand is readable (VERR) or writable (VERW) from the current privilege level (CPL). The source operand is a 16-bit register or a memory location that contains the segment selector for the segment to be verified. If the segment is accessible and readable (VERR) or writable (VERW), the ZF flag is set; otherwise, the ZF flag is cleared. Code segments are never verified as writable. This check cannot be performed on system segments.

To set the ZF flag, the following conditions must be met:

- The segment selector is not null.
- The selector must denote a descriptor within the bounds of the descriptor table (GDT or LDT).
- The selector must denote the descriptor of a code or data segment (not that of a system segment or gate).
- For the VERR instruction, the segment must be readable.
- For the VERW instruction, the segment must be a writable data segment.
- If the segment is not a conforming code segment, the segment’s DPL must be greater than or equal to (have less or the same privilege as) both the CPL and the segment selector’s RPL.

The validation performed is the same as is performed when a segment selector is loaded into the DS, ES, FS, or GS register, and the indicated access (read or write) is performed. The segment selector’s value cannot result in a protection exception, enabling the software to anticipate possible segment access problems.

**Operation**

```plaintext
IF SRC[Offset] > (GDTR(Limit) OR (LDTR(Limit))
   THEN
       ZF ← 0
Read segment descriptor;
IF SegmentDescriptor(DescriptorType) ← 0 (* system segment *)
   OR (SegmentDescriptor(DescriptorType) ≠ conforming code segment)
   AND (CPL > DPL) OR (RPL > DPL)
   THEN
       ZF ← 0
```
Verr, Verw—Verify a Segment for Reading or Writing
(Continued)

ELSE
  IF ((Instruction ← VERR) AND (segment ← readable))
    OR ((Instruction ← VERW) AND (segment ← writable))
    THEN
      ZF ← 1;
  FI;
FI;

Flags Affected
The ZF flag is set to 1 if the segment is accessible and readable (VERR) or writable (VERW); otherwise, it is cleared to 0.

Protected Mode Exceptions
The only exceptions generated for these instructions are those related to illegal addressing of the source operand.
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register is used to access memory and it contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.
#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions
#UD The VERR and VERW instructions are not recognized in real-address mode.

Virtual-8086 Mode Exceptions
#UD The VERR and VERW instructions are not recognized in virtual-8086 mode.
WAIT/FWAIT—Wait

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9B</td>
<td>WAIT</td>
<td>Check pending unmasked floating-point exceptions.</td>
</tr>
<tr>
<td>9B</td>
<td>FWAIT</td>
<td>Check pending unmasked floating-point exceptions.</td>
</tr>
</tbody>
</table>

**Description**

Causes the processor to check for and handle pending, unmasked, floating-point exceptions before proceeding. (FWAIT is an alternate mnemonic for the WAIT).

This instruction is useful for synchronizing exceptions in critical sections of code. Coding a WAIT instruction after a floating-point instruction insures that any unmasked floating-point exceptions the instruction may raise are handled before the processor can modify the instruction’s results. See the section titled “Floating-Point Exception Synchronization” in Chapter 8 of the *IA-32 Intel Architecture Software Developer’s Manual, Volume 1*, for more information on using the WAIT/FWAIT instruction.

**Operation**

CheckForPendingUnmaskedFloatingPointExceptions;

**FPU Flags Affected**

The C0, C1, C2, and C3 flags are undefined.

**Floating-Point Exceptions**

None.

**Protected Mode Exceptions**

#NM MP and TS in CR0 is set.

**Real-Address Mode Exceptions**

#NM MP and TS in CR0 is set.

**Virtual-8086 Mode Exceptions**

#NM MP and TS in CR0 is set.

WBINVD—Write Back and Invalidate Cache

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 09</td>
<td>WBINVD</td>
<td>Write back and flush Internal caches; initiate writing-back and flushing of external caches.</td>
</tr>
</tbody>
</table>

**Description**

Writes back all modified cache lines in the processor’s internal cache to main memory and invalidates (flushes) the internal caches. The instruction then issues a special-function bus cycle that directs external caches to also write back modified data and another bus cycle to indicate that the external caches should be invalidated.

After executing this instruction, the processor does not wait for the external caches to complete their write-back and flushing operations before proceeding with instruction execution. It is the responsibility of hardware to respond to the cache write-back and flush signals.

The WBINVD instruction is a privileged instruction. When the processor is running in protected mode, the CPL of a program or procedure must be 0 to execute this instruction. This instruction is also a serializing instruction (see “Serializing Instructions” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3).

In situations where cache coherency with main memory is not a concern, software can use the INVD instruction.

**IA-32 Architecture Compatibility**

The WBINVD instruction is implementation dependent, and its function may be implemented differently on future IA-32 processors. The instruction is not supported on IA-32 processors earlier than the Intel486 processor.

**Operation**

WriteBack(InternalCaches);
Flush(InternalCaches);
SignalWriteBack(ExternalCaches);
SignalFlush(ExternalCaches);
Continue (* Continue execution);

**Flags Affected**

None.

**Protected Mode Exceptions**

#GP(0) If the current privilege level is not 0.
WBINVD—Write Back and Invalidate Cache (Continued)

Real-Address Mode Exceptions
None.

Virtual-8086 Mode Exceptions
#GP(0) The WBINVD instruction cannot be executed at the virtual-8086 mode.
WRMSR—Write to Model Specific Register

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F 30</td>
<td>WRMSR</td>
<td>Write the value in EDX:EAX to MSR specified by ECX</td>
</tr>
</tbody>
</table>

Description

Writes the contents of registers EDX:EAX into the 64-bit model specific register (MSR) specified in the ECX register. The input value loaded into the ECX register is the address of the MSR to be written to. The contents of the EDX register are copied to high-order 32 bits of the selected MSR and the contents of the EAX register are copied to low-order 32 bits of the MSR. Undefined or reserved bits in an MSR should be set to the values previously read.

This instruction must be executed at privilege level 0 or in real-address mode; otherwise, a general protection exception #GP(0) will be generated. Specifying a reserved or unimplemented MSR address in ECX will also cause a general protection exception.

When the WRMSR instruction is used to write to an MTRR, the TLBs are invalidated, including the global entries (see “Translation Lookaside Buffers (TLBs)” in Chapter 3 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3). (MTRRs are an implementation-specific feature of the Pentium Pro processor.)

The MSRs control functions for testability, execution tracing, performance-monitoring and machine check errors. Appendix B, Model-Specific Registers (MSRs), in the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, lists all the MSRs that can be read with this instruction and their addresses. Note that each processor family has its own set of MSRs.

The WRMSR instruction is a serializing instruction (see “Serializing Instructions” in Chapter 8 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3).

The CPUID instruction should be used to determine whether MSRs are supported (EDX[5]=1) before using this instruction.

IA-32 Architecture Compatibility

The MSRs and the ability to read them with the WRMSR instruction were introduced into the IA-32 Architecture with the Pentium processor. Execution of this instruction by an IA-32 processor earlier than the Pentium processor results in an invalid opcode exception #UD.

Operation

\[
\text{MSR}[\text{ECX}] \leftarrow \text{EDX:EAX};
\]

Flags Affected

None.
WRMSR—Write to Model Specific Register (Continued)

Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.
If the value in ECX specifies a reserved or unimplemented MSR address.

Real-Address Mode Exceptions

#GP If the value in ECX specifies a reserved or unimplemented MSR address.

Virtual-8086 Mode Exceptions

#GP(0) The WRMSR instruction is not recognized in virtual-8086 mode.
XADD—Exchange and Add

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F C0 /r</td>
<td>XADD r/m8, r8</td>
<td>Exchange r8 and r/m8; load sum into r/m8.</td>

<td>XADD r/m16, r16</td>
<td>Exchange r16 and r/m16; load sum into r/m16.</td>
</tr>
<tr>
<td>0F C1 /r</td>
<td>XADD r/m32, r32</td>
<td>Exchange r32 and r/m32; load sum into r/m32.</td>
</tr>
</tbody>
</table>

Description

Exchanges the first operand (destination operand) with the second operand (source operand), then loads the sum of the two values into the destination operand. The destination operand can be a register or a memory location; the source operand is a register.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

IA-32 Architecture Compatibility

IA-32 processors earlier than the Intel486 processor do not recognize this instruction. If this instruction is used, you should provide an equivalent code sequence that runs on earlier processors.

Operation

\[
\text{TEMP} \leftarrow \text{SRC} + \text{DEST} \\
\text{SRC} \leftarrow \text{DEST} \\
\text{DEST} \leftarrow \text{TEMP}
\]

Flags Affected

The CF, PF, AF, SF, ZF, and OF flags are set according to the result of the addition, which is stored in the destination operand.

Protected Mode Exceptions

- #GP(0) If the destination is located in a nonwritable segment.
- If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- If the DS, ES, FS, or GS register contains a null segment selector.
- #SS(0) If a memory operand effective address is outside the SS segment limit.
- #PF(fault-code) If a page fault occurs.
- #AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
XADD—Exchange and Add (Continued)

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.

<td>Exchange r32 with doubleword from r/m32</td>
</tr>
<tr>
<td>87 /r</td>
<td>XCHG r32, r/m32</td>
<td>Exchange doubleword from r/m32 with r32</td>
</tr>
</tbody>
</table>

Description

Exchanges the contents of the destination (first) and source (second) operands. The operands can be two general-purpose registers or a register and a memory location. If a memory operand is referenced, the processor’s locking protocol is automatically implemented for the duration of the exchange operation, regardless of the presence or absence of the LOCK prefix or of the value of the IOPL. (See the LOCK prefix description in this chapter for more information on the locking protocol.)

This instruction is useful for implementing semaphores or similar data structures for process synchronization. (See “Bus Locking” in Chapter 7 of the IA-32 Intel Architecture Software Developer’s Manual, Volume 3, for more information on bus locking.)

The XCHG instruction can also be used instead of the BSWAP instruction for 16-bit operands.

Operation

TEMP ← DEST
DEST ← SRC
SRC ← TEMP

Flags Affected

None.

Protected Mode Exceptions

#GP(0) If either operand is in a nonwritable segment.
If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
If the DS, ES, FS, or GS register contains a null segment selector.
XCHG—Exchange Register/Memory with Register (Continued)

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made.
INSTRUCTION SET REFERENCE

XLAT/XLATB—Table Look-up Translation

Description
Locates a byte entry in a table in memory, using the contents of the AL register as a table index, then copies the contents of the table entry back into the AL register. The index in the AL register is treated as an unsigned integer. The XLAT and XLATB instructions get the base address of the table in memory from either the DS:EBX or the DS:BX registers (depending on the address-size attribute of the instruction, 32 or 16, respectively). (The DS segment may be overridden with a segment override prefix.)

At the assembly-code level, two forms of this instruction are allowed: the “explicit-operand” form and the “no-operand” form. The explicit-operand form (specified with the XLAT mnemonic) allows the base address of the table to be specified explicitly with a symbol. This explicit-operands form is provided to allow documentation; however, note that the documentation provided by this form can be misleading. That is, the symbol does not have to specify the correct base address. The base address is always specified by the DS:(E)BX registers, which must be loaded correctly before the XLAT instruction is executed.

The no-operands form (XLATB) provides a “short form” of the XLAT instructions. Here also the processor assumes that the DS:(E)BX registers contain the base address of the table.

Operation
IF AddressSize ← 16
   THEN
      AL ← (DS:BX + ZeroExtend(AL))
   ELSE (* AddressSize ← 32 *)
      AL ← (DS:EBX + ZeroExtend(AL));
   FI;

Flags Affected
None.

Protected Mode Exceptions
#GP(0) If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
   If the DS, ES, FS, or GS register contains a null segment selector.
#SS(0) If a memory operand effective address is outside the SS segment limit.
#PF(fault-code) If a page fault occurs.

XLAT/XLATB—Table Look-up Translation (Continued)

Real-Address Mode Exceptions

- **#GP** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS** If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

- **#GP(0)** If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
- **#SS(0)** If a memory operand effective address is outside the SS segment limit.
- **#PF(fault-code)** If a page fault occurs.
**XOR—Logical Exclusive OR**

### Description
Performs a bitwise exclusive OR (XOR) operation on the destination (first) and source (second) operands and stores the result in the destination operand location. The source operand can be an immediate, a register, or a memory location; the destination operand can be a register or a memory location. (However, two memory operands cannot be used in one instruction.) Each bit of the result is 1 if the corresponding bits of the operands are different; each bit is 0 if the corresponding bits are the same.

This instruction can be used with a LOCK prefix to allow the instruction to be executed atomically.

### Operation
DEST ← DEST XOR SRC;

### Flags Affected
The OF and CF flags are cleared; the SF, ZF, and PF flags are set according to the result. The state of the AF flag is undefined.
XOR—Logical Exclusive OR (Continued)

Protected Mode Exceptions

#GP(0) If the destination operand points to a nonwritable segment.

If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

If the DS, ES, FS, or GS register contains a null segment selector.

#SS(0) If a memory operand effective address is outside the SS segment limit.

#PF(fault-code) If a page fault occurs.

#AC(0) If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.

Real-Address Mode Exceptions

#GP If a memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.

#SS If a memory operand effective address is outside the SS segment limit.

Virtual-8086 Mode Exceptions

  - If memory operand is not aligned on a 16-byte boundary, regardless of segment.
- #SS(0) For an illegal address in the SS segment.
- #PF(fault-code) For a page fault.
- #NM If TS in CR0 is set.
- #XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.
- #UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.
  - If EM in CR0 is set.
  - If OSFXSR in CR4 is 0.
  - If CPUID feature flag SSE is 0.
XORPS—Bitwise Logical XOR for Single-Precision Floating-Point Values (Continued)

Real-Address Mode Exceptions

#GP(0) If memory operand is not aligned on a 16-byte boundary, regardless of segment.

Interrupt 13 If any part of the operand lies outside the effective address space from 0 to FFFFH.

#NM If TS in CR0 is set.

#XM If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 1.

#UD If an unmasked SIMD floating-point exception and OSXMMEXCPT in CR4 is 0.

If EM in CR0 is set.

If OSFXSR in CR4 is 0.

If CPUID feature flag SSE is 0.

Virtual-8086 Mode Exceptions

Same exceptions as in Real Address Mode

#PF(fault-code) For a page fault.
Opcode Map
The opcode tables in this chapter are provided to aid in interpreting IA-32 architecture object code. The instructions are divided into three encoding groups: 1-byte opcode encodings, 2-byte opcode encodings, and escape (floating-point) encodings. The 1- and 2-byte opcode encodings are used to encode integer, system, MMX technology, SSE, and SSE2 instructions. The opcode maps for these instructions are given in Table A-2 through A-6. Section A.2.1., “One-Byte Opcode Instructions” through Section A.2.4., “Opcode Extensions For One- And Two-byte Op-codes” give instructions for interpreting 1- and 2-byte opcode maps. The escape encodings are used to encode floating-point instructions. The opcode maps for these instructions are given in Table A-7 through A-22. Section A.2.5., “Escape Opcode Instructions” gives instructions for interpreting the escape opcode maps.

The opcode tables in this section aid in interpreting IA-32 processor object code. Use the four high-order bits of the opcode as an index to a row of the opcode table; use the four low-order bits as an index to a column of the table. If the opcode is 0FH, refer to the 2-byte opcode table and use the second byte of the opcode to index the rows and columns of that table.

The escape (ESC) opcode tables for floating-point instructions identify the eight high-order bits of the opcode at the top of each page. If the accompanying ModR/M byte is in the range 00H through BFH, bits 3 through 5 identified along the top row of the third table on each page, along with the REG bits of the ModR/M, determine the opcode. ModR/M bytes outside the range 00H through BFH are mapped by the bottom two tables on each page.

Refer to Chapter 2, Instruction Format for detailed information on the ModR/M byte, register values, and the various addressing forms.

A.1. KEY TO ABBREVIATIONS

Operands are identified by a two-character code of the form Zz. The first character, an uppercase letter, specifies the addressing method; the second character, a lowercase letter, specifies the type of operand.

A.1.1. Codes for Addressing Method

The following abbreviations are used for addressing methods:

A Direct address. The instruction has no ModR/M byte; the address of the operand is encoded in the instruction; and no base register, index register, or scaling factor can be applied (for example, far JMP (EA)).

C The reg field of the ModR/M byte selects a control register (for example, MOV (0F20, 0F22)).
The reg field of the ModR/M byte selects a debug register (for example, MOV (0F21,0F23)).

A ModR/M byte follows the opcode and specifies the operand. The operand is either a general-purpose register or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, or a displacement.

EFLAGS Register.

The reg field of the ModR/M byte selects a general register (for example, AX (000)).

Immediate data. The operand value is encoded in subsequent bytes of the instruction.

The instruction contains a relative offset to be added to the instruction pointer register (for example, JMP (0E9), LOOP).

The ModR/M byte may refer only to memory (for example, BOUND, LES, LDS, LSS, LFS, LGS, CMPXCHG8B).

The instruction has no ModR/M byte; the offset of the operand is coded as a word or double word (depending on address size attribute) in the instruction. No base register, index register, or scaling factor can be applied (for example, MOV (A0–A3)).

The reg field of the ModR/M byte selects a packed quadword MMX technology register.

A ModR/M byte follows the opcode and specifies the operand. The operand is either an MMX technology register or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, and a displacement.

The mod field of the ModR/M byte may refer only to a general register (for example, MOV (0F20-0F24, 0F26)).

The reg field of the ModR/M byte selects a segment register (for example, MOV (8C,8E)).

The reg field of the ModR/M byte selects a test register (for example, MOV (0F24,0F26)).

The reg field of the ModR/M byte selects a 128-bit XMM register.

A ModR/M byte follows the opcode and specifies the operand. The operand is either a 128-bit XMM register or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, and a displacement

Memory addressed by the DS:SI register pair (for example, MOV, CMPS, OUTS, or LODS).

Memory addressed by the ES:DI register pair (for example, MOV, CMPS, INS, STOS, or SCAS).
A.1.2. Codes for Operand Type

The following abbreviations are used for operand types:

a  Two one-word operands in memory or two double-word operands in memory, depending on operand-size attribute (used only by the BOUND instruction).
b  Byte, regardless of operand-size attribute.
c  Byte or word, depending on operand-size attribute.
d  Doubleword, regardless of operand-size attribute.
dq Double-quadword, regardless of operand-size attribute.
p  32-bit or 48-bit pointer, depending on operand-size attribute.
pi Quadword MMX technology register (e.g., mm0)
ps 128-bit packed single-precision floating-point data.
q  Quadword, regardless of operand-size attribute.
s  6-byte pseudo-descriptor.
ss Scalar element of a 128-bit packed single-precision floating data.
si Doubleword integer register (e.g., eax)
v  Word or doubleword, depending on operand-size attribute.
w  Word, regardless of operand-size attribute.

A.1.3. Register Codes

When an operand is a specific register encoded in the opcode, the register is identified by its name (for example, AX, CL, or ESI). The name of the register indicates whether the register is 32, 16, or 8 bits wide. A register identifier of the form eXX is used when the width of the register depends on the operand-size attribute. For example, eAX indicates that the AX register is used when the operand-size attribute is 16, and the EAX register is used when the operand-size attribute is 32.

A.2. OPCODE LOOK-UP EXAMPLES

This section provides several examples to demonstrate how the following opcode maps are used. Refer to the introduction to Chapter 3, Instruction Set Reference, for detailed information on the ModR/M byte, register values, and the various addressing forms.
A.2.1. One-Byte Opcode Instructions

The opcode maps for 1-byte opcodes are shown in Table A-2 and A-3. Looking at the 1-byte opcode maps, the instruction and its operands can be determined from the hexadecimal opcode. For example:

**Opcode: 030500000000H**

<table>
<thead>
<tr>
<th>LSB address</th>
<th>03</th>
<th>05</th>
<th>00</th>
<th>00</th>
<th>MSB address</th>
</tr>
</thead>
</table>

Opcode 030500000000H for an ADD instruction can be interpreted from the 1-byte opcode map as follows. The first digit (0) of the opcode indicates the row, and the second digit (3) indicates the column in the opcode map tables. The first operand (type Gv) indicates a general register that is a word or doubleword depending on the operand-size attribute. The second operand (type Ev) indicates that a ModR/M byte follows that specifies whether the operand is a word or doubleword general-purpose register or a memory address. The ModR/M byte for this instruction is 05H, which indicates that a 32-bit displacement follows (00000000H). The reg/opcode portion of the ModR/M byte (bits 3 through 5) is 000, indicating the EAX register. Thus, it can be determined that the instruction for this opcode is ADD EAX, mem_op, and the offset of mem_op is 00000000H.

Some 1- and 2-byte opcodes point to “group” numbers. These group numbers indicate that the instruction uses the reg/opcode bits in the ModR/M byte as an opcode extension (refer to Section A.2.4., “Opcode Extensions For One- And Two-byte Opcodes”).

A.2.2. Two-Byte Opcode Instructions

Instructions that begin with 0FH can be found in the two-byte opcode maps given in Table A-4 and A-5. The second opcode byte is used to reference a particular row and column in the tables. For example, the opcode 0FA4050000000003H is located on the two-byte opcode map in row A, column 4. This opcode indicates a SHLD instruction with the operands Ev, Gv, and Ib. These operands are defined as follows:

- **Ev** The ModR/M byte follows the opcode to specify a word or doubleword operand
- **Gv** The reg field of the ModR/M byte selects a general-purpose register
- **Ib** Immediate data is encoded in the subsequent byte of the instruction.

The third byte is the ModR/M byte (05H). The mod and opcode/reg fields indicate that a 32-bit displacement follows, located in the EAX register, and is the source.

The next part of the opcode is the 32-bit displacement for the destination memory operand (00000000H), and finally the immediate byte representing the count of the shift (03H).

By this breakdown, it has been shown that this opcode represents the instruction:

**SHLD DS:00000000H, EAX, 3**
The next part of the SHLD opcode is the 32-bit displacement for the destination memory operand (00000000H), which is followed by the immediate byte representing the count of the shift (03H). By this breakdown, it has been shown that the opcode 0FA405000000003H represents the instruction:

SHLD DS:00000000H, EAX, 3.

Lower case is used in the following tables to highlight the mnemonics added by MMX technology, SSE, and SSE2 instructions.

A.2.3. Opcode Map Notes

Table A-1 contains notes on particular encodings. These notes are indicated in the following Opcode Maps (Table A-2 through A-6) by superscripts.

For the One-byte Opcode Maps (Table A-2 through A-3), grey shading indicates instruction groupings.

A.2.4. Opcode Extensions For One- And Two-byte Opcodes

Some of the 1-byte and 2-byte opcodes use bits 5, 4, and 3 of the ModR/M byte (the nnn field in Figure A-1) as an extension of the opcode. Those opcodes that have opcode extensions are indicated in Table A-6 with group numbers (Group 1, Group 2, etc.). The group numbers (ranging from 1 to A) provide an entry point into Table A-6 where the encoding of the opcode extension field can be found. For example, the ADD instruction with a 1-byte opcode of 80H is a Group 1 instruction. Table A-6 indicates that the opcode extension that must be encoded in the ModR/M byte for this instruction is 000B.

**GENERAL NOTE:**

All blanks in the opcode map are reserved and should not be used. Do not depend on the operation of these undefined opcodes.
A.2.5. Escape Opcode Instructions

The opcode maps for the escape instruction opcodes (floating-point instruction opcodes) are given in Table A-7 through A-22. These opcode maps are grouped by the first byte of the opcode from D8 through DF. Each of these opcodes has a ModR/M byte. If the ModR/M byte is within the range of 00H through BFH, bits 5, 4, and 3 of the ModR/M byte are used as an opcode extension, similar to the technique used for 1-and 2-byte opcodes (refer to Section A.2.4., “Opcode Extensions For One-And Two-byte Opcodes”). If the ModR/M byte is outside the range of 00H through BFH, the entire ModR/M byte is used as an opcode extension.

A.2.5.1. OPCODES WITH MODR/M BYTES IN THE 00H THROUGH BFH RANGE

The opcode DD0504000000H can be interpreted as follows. The instruction encoded with this opcode can be located in Section A.2.5.8., “Escape Opcodes with DD as First Byte”. Since the ModR/M byte (05H) is within the 00H through BFH range, bits 3 through 5 (000) of this byte indicate the opcode to be for an FLD double-real instruction (refer to Table A-9). The double-real value to be loaded is at 00000004H, which is the 32-bit displacement that follows and belongs to this opcode.

A.2.5.2. OPCODES WITH MODR/M BYTES OUTSIDE THE 00H THROUGH BFH RANGE

The opcode D8C1H illustrates an opcode with a ModR/M byte outside the range of 00H through BFH. The instruction encoded here, can be located in Section A.2.4., “Opcode Extensions For One-And Two-byte Opcodes”. In Table A-8, the ModR/M byte C1H indicates row C, column 1, which is an FADD instruction using ST(0), ST(1) as the operands.

A.2.5.3. ESCAPE OPCODES WITH D8 AS FIRST BYTE

Table A-7 and A-8 contain the opcodes maps for the escape instruction opcodes that begin with D8H. Table A-7 shows the opcode map if the accompanying ModR/M byte within the range of 00H through BFH. Here, the value of bits 5, 4, and 3 (the nnn field in Figure A-1) selects the instruction.

<table>
<thead>
<tr>
<th>nnn Field of ModR/M Byte (refer to Figure A.2.4.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
</tr>
<tr>
<td>FADD single-real</td>
</tr>
</tbody>
</table>

1. Table A-7. D8 Opcode Map When ModR/M Byte is Within 00H to BFH
Table A-8 shows the opcode map if the accompanying ModR/M byte is outside the range of 00H to BFH. In this case the first digit of the ModR/M byte selects the row in the table and the second digit selects the column.

</table>

The above table shows the opcode map when the ModR/M byte is outside the range of 00H to BFH. The first digit of the ModR/M byte selects the row and the second digit selects the column.
A.2.5.4. ESCAPE OPCODES WITH D9 AS FIRST BYTE

Table A-9 and A-10 contain opcodes maps for escape instruction opcodes that begin with D9H. Table A-9 shows the opcode map if the accompanying ModR/M byte is within the range of 00H through BFH. Here, the value of bits 5, 4, and 3 (the Figure A-1 nnn field) selects the instruction.

| nnn Field of ModR/M Byte (refer to Figure A-1) |
|---|---|---|---|---|---|---|---|
| 000 | 001 | 010 | 011 | 100 | 101 | 110 | 111 |
| FLD single-real | FST single-real | FSTP single-real | FLDENV 14/28 bytes | FLDCW 2 bytes | FSTENV 14/28 bytes | FSTCW 2 bytes |

NOTE:
1. All blanks in the opcode map are reserved and should not be used. Do not depend on the operation of these undefined opcodes.

Table A-10 shows the opcode map if the accompanying ModR/M byte is outside the range of 00H to BFH. In this case the first digit of the ModR/M byte selects the row in the table and the second digit selects the column.

**NOTE:**
1. All blanks in the opcode map are reserved and should not be used. Do not depend on the operation of these undefined opcodes.

**A.2.5.10. ESCAPE OP CODES WITH DF AS FIRST BYTE**

Table A-21 and A-22 contain the opcodes maps for the escape instruction opcodes that begin with DFH. Table A-21 shows the opcode map if the accompanying ModR/M byte within the range of 00H through BFH. Here, the value of bits 5, 4, and 3 (the nnn field in Figure A-1) selects the instruction.
**Table A-21. DF Opcode Map When ModR/M Byte is Within 00H to BFH**

Instruction Formats and Encodings
APPENDIX B
INSTRUCTION FORMATS AND ENCODINGS

This appendix shows the machine instruction formats and encodings of the IA-32 architecture instructions. The first section describes in detail the IA-32 architecture's machine instruction format. The following sections show the formats and encoding of the general-purpose, MMX, P6 family, SSE, SSE2, and x87 FPU instructions.

B.1. MACHINE INSTRUCTION FORMAT

All Intel Architecture instructions are encoded using subsets of the general machine instruction format shown in Figure B-1. Each instruction consists of an opcode, a register and/or address mode specifier (if required) consisting of the ModR/M byte and sometimes the scale-index-base (SIB) byte, a displacement (if required), and an immediate data field (if required).

The primary opcode for an instruction is encoded in one or two bytes of the instruction. Some instructions also use an opcode extension field encoded in bits 5, 4, and 3 of the ModR/M byte. Within the primary opcode, smaller encoding fields may be defined. These fields vary according to the class of operation being performed. The fields define such information as register encoding, conditional test performed, or sign extension of immediate byte.

Almost all instructions that refer to a register and/or memory operand have a register and/or address mode byte following the opcode. This byte, the ModR/M byte, consists of the mod field, the reg field, and the R/M field. Certain encodings of the ModR/M byte indicate that a second address mode byte, the SIB byte, must be used.

If the selected addressing mode specifies a displacement, the displacement value is placed immediately following the ModR/M byte or SIB byte. If a displacement is present, the possible sizes are 8, 16, or 32 bits.

If the instruction specifies an immediate operand, the immediate value follows any displacement bytes. An immediate operand, if specified, is always the last field of the instruction.
Table B-1 lists several smaller fields or bits that appear in certain instructions, sometimes within the opcode bytes themselves. The following tables describe these fields and bits and list the allowable values. All of these fields (except the d bit) are shown in the general-purpose instruction formats given in Table B-10.

### Table B-1. Special Fields Within Instruction Encodings

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>

<td>Specifies a special-purpose (control or debug) register (see Table B-7)</td>
<td>3</td>
</tr>
<tr>
<td>tttn</td>
<td>For conditional instructions, specifies a condition asserted or a condition negated (see Table B-8)</td>
<td>4</td>
</tr>
<tr>
<td>d</td>
<td>Specifies direction of data operation (see Table B-9)</td>
<td>1</td>
</tr>
</tbody>
</table>

#### B.1.1. Reg Field (reg)

The reg field in the ModR/M byte specifies a general-purpose register operand. The group of registers specified is modified by the presence of and state of the w bit in an encoding (see Table B-4). Table B-2 shows the encoding of the reg field when the w bit is not present in an encoding, and Table B-3 shows the encoding of the reg field when the w bit is present.

### Table B-2. Encoding of reg Field When w Field is Not Present in Instruction

<table>
<thead>
<tr>
<th>reg Field</th>

<td>ESI</td>
</tr>
<tr>
<td>111</td>
<td>DI</td>
<td>EDI</td>
</tr>
</tbody>
</table>
**INSTRUCTION FORMATS AND ENCODINGS**

B.1.2. Encoding of Operand Size Bit (w)

The current operand-size attribute determines whether the processor is performing 16-or 32-bit operations. Within the constraints of the current operand-size attribute, the operand-size bit (w) can be used to indicate operations on 8-bit operands or the full operand size specified with the operand-size attribute (16 bits or 32 bits). Table B-4 shows the encoding of the w bit depending on the current operand-size attribute.

<table>
<thead>
<tr>
<th>w Bit</th>
<th>Operand Size When Operand-Size Attribute is 16 bits</th>
<th>Operand Size When Operand-Size Attribute is 32 bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8 Bits</td>
<td>8 Bits</td>
</tr>
<tr>
<td>1</td>
<td>16 Bits</td>
<td>32 Bits</td>
</tr>
</tbody>
</table>

B.1.3. Sign Extend (s) Bit

The sign-extend (s) bit occurs primarily in instructions with immediate data fields that are being extended from 8 bits to 16 or 32 bits. Table B-5 shows the encoding of the s bit.

<table>
<thead>
<tr>
<th>s</th>
<th>Effect on 8-Bit Immediate Data</th>
<th>Effect on 16- or 32-Bit Immediate Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>1</td>
<td>Sign-extend to fill 16-bit or 32-bit destination</td>
<td>None</td>
</tr>
</tbody>
</table>
B.1.4. Segment Register Field (sreg)

When an instruction operates on a segment register, the reg field in the ModR/M byte is called the sreg field and is used to specify the segment register. Table B-6 shows the encoding of the sreg field. This field is sometimes a 2-bit field (sreg2) and other times a 3-bit field (sreg3).

* Do not use reserved encodings.

Table B-6. Encoding of the Segment Register (sreg) Field

<table>
<thead>
<tr>
<th>2-Bit sreg2 Field</th>
<th>Segment Register Selected</th>
<th>3-Bit sreg3 Field</th>
<th>Segment Register Selected</th>

</tr>
<tr>
<td></td>
<td></td>
<td>110</td>
<td>Reserved*</td>
</tr>
<tr>
<td></td>
<td></td>
<td>111</td>
<td>Reserved*</td>
</tr>
</tbody>
</table>

* Do not use reserved encodings.

B.1.5. Special-Purpose Register (eee) Field

When the control or debug registers are referenced in an instruction they are encoded in the eee field, which is located in bits 5, 4, and 3 of the ModR/M byte. Table B-7 shows the encoding of the eee field.

* Do not use reserved encodings.
B.1.6. Condition Test Field (tttn)

For conditional instructions (such as conditional jumps and set on condition), the condition test field (tttn) is encoded for the condition being tested for. The ttt part of the field gives the condition to test and the n part indicates whether to use the condition (n = 0) or its negation (n = 1). For 1-byte primary opcodes, the tttn field is located in bits 3,2,1, and 0 of the opcode byte; for 2-byte primary opcodes, the tttn field is located in bits 3,2,1, and 0 of the second opcode byte. Table B-8 shows the encoding of the tttn field.

<table>

<td>Not less than or equal to, Greater than</td>
</tr>
</tbody>
</table>

Table B-8. Encoding of Conditional Test (tttn) Field

B.1.7. Direction (d) Bit

In many two-operand instructions, a direction bit (d) indicates which operand is considered the source and which is the destination. Table B-9 shows the encoding of the d bit. When used for integer instructions, the d bit is located at bit 1 of a 1-byte primary opcode. This bit does not appear as the symbol “d” in Table B-10; instead, the actual encoding of the bit as 1 or 0 is given. When used for floating-point instructions (in Table B-16), the d bit is shown as bit 2 of the first byte of the primary opcode.

B.3. MMX INSTRUCTION FORMATS AND ENCODINGS

All MMX instructions, except the EMMS instruction, use a format similar to the 2-byte Intel Architecture integer format. Details of subfield encodings within these formats are presented below.

B.3.1. Granularity Field (gg)

The granularity field (gg) indicates the size of the packed operands that the instruction is operating on. When this field is used, it is located in bits 1 and 0 of the second opcode byte. Table B-11 shows the encoding of this gg field.

<table>
<thead>
<tr>
<th>gg</th>
<th>Granularity of Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Packed Bytes</td>
</tr>
<tr>
<td>01</td>
<td>Packed Words</td>
</tr>
<tr>
<td>10</td>
<td>Packed Doublewords</td>
</tr>
<tr>
<td>11</td>
<td>Quadword</td>
</tr>
</tbody>
</table>

B.3.2. MMX and General-Purpose Register Fields (mmxreg and reg)

When MMX registers (mmxreg) are used as operands, they are encoded in the ModR/M byte in the reg field (bits 5, 4, and 3) and/or the R/M field (bits 2, 1, and 0). Tables 2-1 and 2-2 show the 3-bit encodings used for mmxreg fields.

If an MMX instruction operates on a general-purpose register (reg), the register is encoded in the R/M field of the ModR/M byte. Tables 2-1 and 2-2 show the encoding of general-purpose registers when used in MMX instructions.

B.3.3. MMX Instruction Formats and Encodings Table

Table B-12 shows the formats and encodings of the integer instructions.

</tr>
</tbody>
</table>
NOTES:
1. The pack instructions perform saturation from signed packed data of one type to signed or unsigned data of the next smaller type.
2. The format of the shift instructions has one additional format to support shifting by immediate shift-counts. The shift operations are not supported equally for all data types.

B.4. P6 FAMILY INSTRUCTION FORMATS AND ENCODINGS

Table B-13 shows the formats and encodings for several instructions that were introduced into the IA-32 architecture in the P6 family processors.

<table>

Table B-12. MMX Instruction Formats and Encodings (Contd.)
INSTRUCTION FORMATS AND ENCODINGS

B.5. SSE INSTRUCTION FORMATS AND ENCODINGS

The SSE instructions use the ModR/M format and are preceded by the 0FH prefix byte. In general, operations are not duplicated to provide two directions (that is, separate load and store variants).

The following three tables (Tables B-14, B-15, and B-16) show the formats and encodings for the SSE SIMD floating-point, SIMD integer, and cacheability and memory ordering instructions, respectively.

B.6. SSE2 INSTRUCTION FORMATS AND ENCODINGS

The SSE2 instructions use the ModR/M format and are preceded by the 0FH prefix byte. In general, operations are not duplicated to provide two directions (that is, separate load and store variants).

The following three tables show the formats and encodings for the SSE2 SIMD floating-point, SIMD integer, and cacheability instructions, respectively.

B.6.1. Granularity Field (gg)

The granularity field (gg) indicates the size of the packed operands that the instruction is operating on. When this field is used, it is located in bits 1 and 0 of the second opcode byte. Table B-19 shows the encoding of this gg field.

<table>

INSTRUCTION FORMATS AND ENCODINGS

B.7. FLOATING-POINT INSTRUCTION FORMATS AND ENCODINGS

Table B-21 shows the five different formats used for floating-point instructions. In all cases, instructions are at least two bytes long and begin with the bit pattern 11011.

Table B-21. General Floating-Point Instruction Formats

<table>
<thead>
<tr>
<th>Instruction</th>
<th>First Byte</th>
<th>Second Byte</th>
<th>Optional Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11011</td>
<td>OPA 1 mod 1 OPB r/m</td>
<td>s-i-b disp</td>
</tr>
<tr>
<td>2</td>
<td>11011</td>
<td>MF OPA mod OPB r/m</td>
<td>s-i-b disp</td>
</tr>
<tr>
<td>3</td>
<td>11011</td>
<td>d P OPA mod OPB R ST(i)</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>11011</td>
<td>0 0 1 1 1 1 OP</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>11011</td>
<td>0 1 1 1 1 1 OP</td>
<td></td>
</tr>
</tbody>
</table>

MF = Memory Format
00 — 32-bit real
01 — 32-bit integer
10 — 64-bit real
11 — 16-bit integer

P = Pop
0 — Do not pop stack
1 — Pop stack after operation

d = Destination
0 — Destination is ST(0)
1 — Destination is ST(i)

R XOR d = 0 — Destination OP Source
R XOR d = 1 — Source OP Destination

ST(i) = Register stack element i
000 = Stack Top
001 = Second stack element
·
·
111 = Eighth stack element

The Mod and R/M fields of the ModR/M byte have the same interpretation as the corresponding fields of the integer instructions. The SIB byte and disp (displacement) are optionally present in instructions that have Mod and R/M fields. Their presence depends on the values of Mod and R/M, as for integer instructions.

Table B-22 shows the formats and encodings of the floating-point instructions.

Intel C/C++ Compiler
Intrinsics and
Functional
Equivalents
APPENDIX C
INTEL C/C++ COMPILER_INTRINSICS AND
FUNCTIONAL EQUIVALENTS

The two tables in this chapter itemize the Intel C/C++ compiler intrinsics and functional equivalents for the Intel MMX technology instructions and SSE and SSE2 instructions.

There may be additional intrinsics that do not have an instruction equivalent. It is strongly recommended that the reader reference the compiler documentation for the complete list of supported intrinsics. Please refer to the Intel C/C++ Compiler User's Guide With Support for the Streaming SIMD Extensions 2 (Order Number 718195-2001). Appendix C catalogs use of these intrinsics.

The Section 3.1.3., “Intel C/C++ Compiler Intrinsics Equivalents” has more general supporting information for the following tables.

Table C-1 presents simple intrinsics, and Table C-2 presents composite intrinsics. Some intrinsics are “composites” because they require more than one instruction to implement them.

Intel C/C++ Compiler intrinsic names reflect the following naming conventions:

_mm_<intrin_op>_<suffix>

where:

<intrin_op> Indicates the intrinsics basic operation; for example, add for addition and sub for subtraction

<suffix> Denotes the type of data operated on by the instruction. The first one or two letters of each suffix denotes whether the data is packed (p), extended packed (ep), or scalar (s). The remaining letters denote the type:

s single-precision floating point
d double-precision floating point
i128 signed 128-bit integer
i64 signed 64-bit integer
u64 unsigned 64-bit integer
i32 signed 32-bit integer
u32 unsigned 32-bit integer

APPENDIX C
INTEL C/C++ COMPILER_INTRINSICS AND
FUNCTIONAL EQUIVALENTS

The two tables in this chapter itemize the Intel C/C++ compiler intrinsics and functional equivalents for the Intel MMX technology instructions and SSE and SSE2 instructions.

There may be additional intrinsics that do not have an instruction equivalent. It is strongly recommended that the reader reference the compiler documentation for the complete list of supported intrinsics. Please refer to the Intel C/C++ Compiler User's Guide With Support for the Streaming SIMD Extensions 2 (Order Number 718195-2001). Appendix C catalogs use of these intrinsics.

The Section 3.1.3., “Intel C/C++ Compiler Intrinsics Equivalents” has more general supporting information for the following tables.

Table C-1 presents simple intrinsics, and Table C-2 presents composite intrinsics. Some intrinsics are “composites” because they require more than one instruction to implement them.

Intel C/C++ Compiler intrinsic names reflect the following naming conventions:

_mm_<intrin_op>_<suffix>

where:

<intrin_op> Indicates the intrinsics basic operation; for example, add for addition and sub for subtraction

<suffix> Denotes the type of data operated on by the instruction. The first one or two letters of each suffix denotes whether the data is packed (p), extended packed (ep), or scalar (s). The remaining letters denote the type:

s single-precision floating point
d double-precision floating point
i128 signed 128-bit integer
i64 signed 64-bit integer
u64 unsigned 64-bit integer
i32 signed 32-bit integer
u32 unsigned 32-bit integer
INTEL C/C++ COMPILER INTRINSICS AND FUNCTIONAL

i16  signed 16-bit integer
u16  unsigned 16-bit integer
i8   signed 8-bit integer
u8   unsigned 8-bit integer

The variable r is generally used for the intrinsic's return value. A number appended to a variable
name indicates the element of a packed object. For example, r0 is the lowest word of r. Some
intrinsics are “composites” because they require more than one instruction to implement them.

The packed values are represented in right-to-left order, with the lowest value being used for
scalar operations. Consider the following example operation:

double a[2] = {1.0, 2.0};
__m128d t = _mm_load_pd(a);

The result is the same as either of the following:
__m128d t = _mm_set_pd(2.0, 1.0);
__m128d t = _mm_setr_pd(1.0, 2.0);

In other words, the XMM register that holds the value t will look as follows:

127---------------------------------0
   | 2.0 | 1.0 |
----------------------------------

The “scalar” element is 1.0. Due to the nature of the instruction, some intrinsics require their
arguments to be immediates (constant integer literals).

To use an intrinsic in your code, insert a line with the following syntax:
data_type intrinsic_name (parameters)

Where:

data_type          Is the return data type, which can be either void, int, __m64,
                    __m128, __m128d, __m128i. Only the __mm_empty intrinsic returns
                    void.

intrinsic_name     Is the name of the intrinsic, which behaves like a function that you
can use in your C/C++ code instead of in-lining the actual instruc-
tion.

parameters         Represents the parameters required by each intrinsic.

RC (rounding control) field, x87 FPU control word. 3-238, 3-242, 3-276

RCL instruction 3-660
RCPPS instruction 3-665
RCPS instruction 3-667

RCR instruction 3-660
RDSMR instruction 3-669, 3-673
RDPMC instruction 3-671
RDTSC instruction 3-673
Reg/opcode field, instruction format 2-3
Rounding, round to integer, x87 FPU operation 3-262

RPL field 1-6
ROR instruction 3-660
Rotate operation 3-660

PSADBW instruction 3-602
PSHUFHFW instruction 3-608
PSHUFWF instruction 3-612
PSLDD instruction 3-615
PSLDDQ instruction 3-618
PSLQ instruction 3-621
PSLLW instruction 3-625
PSRAD instruction 3-620
PSRAW instruction 3-620
PSRLD instruction 3-625
PSRLDQ instruction 3-624
PSRLQ instruction 3-625
PSLLW instruction 3-625

Reserved bits 1-6
RET instruction 3-677
ROL instruction 3-660
ROR instruction 3-660
Rotate operation 3-660

PSADBW instruction 3-602
PSHUFHFW instruction 3-608
PSHUFWF instruction 3-612
PSLDD instruction 3-615
PSLDDQ instruction 3-618
PSLQ instruction 3-621
PSLLW instruction 3-625
PSRAD instruction 3-620
PSRAW instruction 3-620
PSRLD instruction 3-625
PSRLDQ instruction 3-624
PSRLQ instruction 3-625
PSLLW instruction 3-625

SAL instruction 3-690
SAR instruction 3-690
SBB instruction 3-389, 3-694
Scale (operand addressing) 2-3
Scale, x87 FPU operation 3-268
SCAS instruction 3-674, 3-696
SCASB instruction 3-696
SCASD instruction 3-696
SCASW instruction 3-696
Segment descriptor, segment limit 3-396
Segmented addressing 1-8
SF (sign) flag, EFLAGS register 3-19, 3-21
SFENCE instruction 3-701
SGDT instruction 3-702
SHAF instruction 3-689
SHL instruction 3-690
SHLD instruction 3-705
SHR instruction 3-690
SHRD instruction 3-707
SHUFPD instruction 3-709
SHUFPS instruction 3-712
SIB byte 3-72
32-bit addressing forms of 2-7
description of 2-3
format of 2-1

SIDT instruction 3-702
Signaling NaN (see SNaN) 3-311

Significand, extracting from floating-point number 3-311

INDEX-6
### INDEX
