Introduction to Compilers Radu Rugina

Lecture 10: Syntax-Directed Definitions 11 Feb 02

Parsing Techniques

- **LL parsing**
 - Computes a Leftmost derivation
 - Builds the derivation top-down
 - LL parsing table indicates which production to use for expanding the rightmost non-terminal
- **LR parsing**
 - Computes a Rightmost derivation
 - Builds the derivation bottom-up
 - Uses a set of LR states and a stack of symbols
 - LR parsing table indicates, for each state, what action to perform (shift/reduce) and what state to go to next
- Use these techniques to construct an AST

CS 412/413 Spring 2002

Introduction to Compilers

2

AST Review

- **Derivation** = sequence of applied productions
 $S \rightarrow E + S \rightarrow 1 + S \rightarrow 1 + E \rightarrow 1 + 2$
- **Parse tree** = graph representation of a derivation
 - Doesn't capture the order of applying the productions
- **Abstract Syntax Tree (AST)** discards unnecessary information from the parse tree

CS 412/413 Spring 2002

Introduction to Compilers

3

AST Data Structures

```
abstract class Expr { }  
class Add extends Expr {  
  Expr left, right;  
  Add(Expr L, Expr R) {  
    left = L; right = R;  
  }  
}  
class Num extends Expr {  
  int value;  
  Num(int v) { value = v; }  
}
```

CS 412/413 Spring 2002

Introduction to Compilers

4

Implicit AST Construction

- LL/LR parsing techniques **implicitly** build the AST
- The parse tree is captured in the derivation
 - LL parsing: AST is implicitly represented by the sequence of applied productions
 - LR parsing: AST is implicitly represented by the sequence of applied reductions
- We want to **explicitly** construct the AST during the parsing phase:
 - add code in the parser to explicitly build the AST

CS 412/413 Spring 2002

Introduction to Compilers

5

AST Construction

- **LL parsing**: extend procedures for nonterminals
- Example:

```
S → E S'  
S' → ε | + S  
E → num | ( S )
```

```
void parse_S() {  
  switch (token) {  
    case num: case '(':  
      parse_E();  
      parse_S'();  
      return;  
    default:  
      throw new ParseError();  
  }  
}  
  
Expr parse_S() {  
  switch (token) {  
    case num: case '(':  
      Expr left = parse_E();  
      Expr right = parse_S'();  
      if (right == null) return left;  
      else return new Add(left, right);  
    default: throw new ParseError();  
  }  
}
```

Introduction to Compilers

6

AST Construction

- LR parsing
 - We need again to add code for explicit AST construction
- AST construction mechanism for LR Parsing
 - Store parts of the tree on the stack
 - For each nonterminal symbol X on stack, also store the sub-tree rooted at X on stack
 - Whenever the parser performs a reduce operation for a production $X \rightarrow \gamma$, create an AST node for X

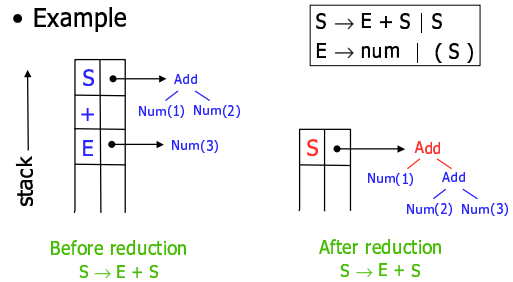

CS 412/413 Spring 2002

Introduction to Compilers

7

AST Construction for LR Parsing

• Example

CS 412/413 Spring 2002

Introduction to Compilers

8

Problems

- Unstructured code: mixed parsing code with AST construction code
- Automatic parser generators
 - The generated parser needs to contain AST construction code
 - How to construct a customized AST data structure using an automatic parser generator?
- May want to perform other actions concurrently with the parsing phase
 - E.g. semantic checks
 - This can reduce the number of compiler passes

CS 412/413 Spring 2002

Introduction to Compilers

9

Syntax-Directed Definition

• Solution: syntax-directed definition

- Extends each grammar production with an associated semantic action (code):

$$S \rightarrow E + S \quad \{ \text{action} \}$$

- The parser generator adds these actions into the generated parser
- Each action is executed when the corresponding production is reduced

CS 412/413 Spring 2002

Introduction to Compilers

10

Semantic Actions

- Actions = code in a programming language
 - Same language as the automatically generated parser
- Examples:
 - Yacc = write actions in C
 - CUP = write actions in Java
- The actions access the parser stack!
 - Parser generators extend the stack of symbols with entries for user-defined structures (e.g. parse trees)
- The action code should be able to refer to the grammar symbols in the production
 - Need a naming scheme...

CS 412/413 Spring 2002

Introduction to Compilers

11

Naming Scheme

- Need special names for grammar symbols to use in the semantic action code
- Need to refer to multiple occurrences of the same nonterminal symbol

$$E \rightarrow E_1 + E_2$$

- Distinguish the nonterminal on the LHS

$$E_0 \rightarrow E + E$$

CS 412/413 Spring 2002

Introduction to Compilers

12

Naming Scheme: CUP

- CUP:
 - Rename nonterminals using distinct, user-defined names:
 - `expr ::= expr:e1 PLUS expr:e2`
 - Use keyword `RESULT` for LHS nonterminal

- CUP Example:

```
expr ::= expr:e1 PLUS expr:e2
      { : RESULT = e1 + e2; ; }
```

Naming Scheme: yacc

- Yacc:
 - Uses keywords: `$1` refers to the first RHS symbol, `$2` refers to the second RHS symbol, etc.
 - Keyword `$$` refers to the LHS nonterminal

- Yacc Example:

```
expr ::= expr PLUS expr { $$ = $1 + $3; }
```

Building the AST

- Use semantic actions to build the AST
- AST is built bottom-up along with parsing

```
non terminal Expr expr;
User-defined type for objects on the stack
Nonterminal name

expr ::= NUM:i { : RESULT = new Num(i.val); ; }
expr ::= expr:e1 PLUS expr:e2 { : RESULT = new Add(e1,e2); ; }
expr ::= expr:e1 MULT expr:e2 { : RESULT = new Mul(e1,e2); ; }
expr ::= LPAR expr:e RPAR { : RESULT = e; ; }
```

Example

`E → num | (E) | E + E | E * E`

- Parser stack stores value of each non-terminal

AST Design

- Keep the AST abstract
- Do not introduce a tree node for every node in parse tree (not very abstract)

AST Design

- Do not use one single class `AST_node`
 - E.g. need information for `if`, `while`, `+`, `*`, `ID`, `NUM`
- ```
class AST_node {
 int node_type;
 AST_node[] children;
 String name; int value; ...etc...
}
```
- Problem: must have fields for every different kind of node with attributes
  - Not extensible, Java type checking no help

## Use Class Hierarchy

- Can use subclassing to solve problem
  - Use an abstract class for each “interesting” set of non-terminals in grammar (e.g. expressions)

$E \rightarrow E + E \mid E * E \mid -E \mid ( E )$

```
abstract class Expr { ... }
class Add extends Expr { Expr left, right; ... }
class Mult extends Expr { Expr left, right; ... }
// or: class BinExpr extends Expr { Oper o; Expr l, r; }
class Minus extends Expr { Expr e; ... }
```

CS 412/413 Spring 2002

Introduction to Compilers

19

## Another Example

$E ::= \text{num} \mid ( E ) \mid E + E \mid \text{id}$   
 $S ::= E ; \mid \text{if } ( E ) S \mid \text{if } ( E ) S \text{ else } S \mid \text{id} = E ; ;$

```
abstract class Expr { ... }
class Num extends Expr { Num(int value) ... }
class Add extends Expr { Add(Expr e1, Expr e2) ... }
class Id extends Expr { Id(String name) ... }
```

```
abstract class Stmt { ... }
class IfS extends Stmt { IfS(Expr c, Stmt s1, Stmt s2) }
class EmptyS extends Stmt { EmptyS() ... }
class AssignS extends Stmt { AssignS(String id, Expr e)... }
```

CS 412/413 Spring 2002

Introduction to Compilers

20

## Other Syntax-Directed Definitions

- Can use syntax-directed definitions to perform **semantic checks** during parsing
  - E.g. type-checking
- **Benefit** = efficiency
  - One single compiler pass for multiple tasks
- **Disadvantage** = unstructured code
  - Mixes parsing and semantic checking phases
  - Perform checks while AST is changing

CS 412/413 Spring 2002

Introduction to Compilers

21

## Type Declaration Example

$D \rightarrow T \text{ id}$       { AddType(id, T.type);  
                                   D.type = T.type; }

$D \rightarrow D_1 , \text{id}$       { AddType(id, D<sub>1</sub>.type);  
                                   D.type = D<sub>1</sub>.type; }

$T \rightarrow \text{int}$               { T.type = intType; }

$T \rightarrow \text{float}$              { T.type = floatType; }

CS 412/413 Spring 2002

Introduction to Compilers

22

## Propagation of Values

- Propagate type attributes while building the AST

CS 412/413 Spring 2002

Introduction to Compilers

23

## Another Example

$D \rightarrow T L$               { AddType(id, T.type);  
                                   D.type = T.type;  
                                   L.type = D.type; }

$T \rightarrow \text{int}$               { T.type = intType; }

$T \rightarrow \text{float}$              { T.type = floatType; }

$L \rightarrow L_1 , \text{id}$         { AddType(id, L<sub>1</sub>.type);  
                                   ??? }

$L \rightarrow \text{id}$                 { AddType(id, ???); }

CS 412/413 Spring 2002

Introduction to Compilers

24

## Propagation of Values

- Propagate values both bottom-up and top-down

CS 412/413 Spring 2002

Introduction to Compilers

25

## Structured Approach

- Separate AST construction from semantic checking phase
- Traverse the AST and perform semantic checks (or other actions) only after the tree has been built and its structure is stable
- This approach is less error-prone
  - It is better when efficiency is not a critical issue

CS 412/413 Spring 2002

Introduction to Compilers

26

## Summary

- Syntax-directed definitions attach semantic actions to grammar productions
- Easy to construct the AST using syntax-directed definitions
- Can use syntax-directed definitions to perform semantic checks
- Separate AST construction from semantic checks or other actions which traverse the AST
