Project 2
Intro Lecture

Sam McCoy
Cornell CS 4411, September 23, 2016
Today’s Lecture

- Administrative Information
- Project 2 Rundown
- Discussion
Project 1 is still being graded – results should be ready by beginning of next week.

Project 2 will be due at 11:59pm on October 6th.
P2 Overview

- Three main parts of P2:
  - Clock Interrupts
  - Add Alarms
    - Implement thread sleep_with_timeout()
  - Multilevel Feedback Queue Scheduler
Where are we now?

- We made a very large assumption in P1
  - Threads will behave and yield the CPU to other threads.
- Issues?
  - Selfish Threads
  - Starvation
- Need the ability to interrupt running threads…
Introducing Interrupts

- Every clock tick the interrupt handler will be called.
- Allows us to schedule a new thread to be run without relying on nice behavior.
- Maskable Interrupts:
  - Minithread_clock_init()
  - Set_interrupt_level()
- Always save old interrupt level!
Disabling Interrupts

- When you need to do something that must be done atomically.
- Typically manipulations on shared data structures.
  - Data structures that can be accessed by multiple threads ‘simultaneously’.
  - Modifying the cleanup queue, ready queue, alarm list.
- Trivial way of achieving correctness: disable interrupts for everything.
  - Why is this a bad idea?
Interrupt Handler - Reminder

- Entry point when a clock interrupt occurs.
- Are there problems if the interrupt handler is interrupted?
  - Yes – accessing shared data structures
  - Solution – disable interrupt in the interrupt handler

CANNOT BLOCK
Semaphore Revisited

- Typical sem_P code:

```c
while (TAS(&lock) == 1);

sem->counter--;
if (sem->counter < 0)
{
    append thread to blocked queue
    atomically unlock and stop
}
else
{
    atomic_clear(&lock);
}
```
Semaphore Revisited

- Typical sem_V code:

```
while (TAS(&lock) == 1);

sem->counter++;
if (sem->counter <= 0)
{
    take one thread from blocked queue
    start the thread
}

atomic_clear(&lock);
```
Semaphore in User Space

-Interrupts can arrive at any time.
-If interrupts arrive while a TAS lock is held:
  - Another thread that tries to acquire the TAS lock will spin until its time quanta is exhausted.
  - Thread holding the TAS lock will eventually regain control and make progress.
  - Progress ensures other threads can eventually get the TAS lock.

```c
while (TAS(&lock) == 1);
sem->counter--;
if (sem->counter < 0)
{
    append thread to blocked queue
    atomically unlock and stop
}
else
    atomic_clear(&lock);
```

```c
while (TAS(&lock) == 1);
sem->counter++;
if (sem->counter <= 0)
{
    take one thread from blocked queue
    start the thread
}
atomic_clear(&lock);
```
Semaphore In Kernel Space

- Typically used to block some thread and wake it up on some condition
  - `minithread_sleep_with_timeout()`
  - wake up the thread after the elapsed time
- Waking up requires calling `sem_V` on that sleep semaphore
- Where is this done?
  - Done in kernel space with interrupts disabled.
Unfortunate Interleaving

- What if user calls `sleep_with_timeout(0)`?
  - `sem_P` is called, and thread blocks itself.
- What if `sem_P` was interrupted just after placing thread on blocked queue but before clearing TAS lock?

User calls `sleep_with_timeout(0)`...

```c
while (TAS(&lock) == 1);
sem->counter--;
if (sem->counter < 0)
{
    append thread to blocked queue
    clock interrupt!
    atomically unlock and stop
}
else
    atomic_clear(&lock);
```

...clock handler tries to wake that thread up

```c
while (TAS(&lock) == 1);
sem->counter++;
if (sem->counter <= 0)
{
    take one thread from blocked queue
    start the thread
}
atomic_clear(&lock);
```

but interrupts are disabled in the clock handler!
Solution

- Disable interrupts for sem_P and sem_V for minithread_sleep
  - Atomicity: sem_P will be done with everything before an interrupt can possibly arrive.
  - If interrupt arrives, acquisition of TAS lock is guaranteed in kernel space.
- What about sem_V?
  - sem_V is called from interrupt handler.
  - Interrupts are already disabled in the handler.
When is this applicable?

- If semaphore will be used in portions of your kernel where interrupts are disabled.
  - Right now: only the sleep semaphore.

- What about cleanup semaphore?
  - Cleanup semaphore is not signaled from any place where interrupts are disabled.
  - Cleanup code should only disable interrupts while accessing the cleanup queue, not for semaphore signaling.
What is the maximum number of unique threads that can run per level?
Scheduling

- Completes 1 sweep over the queue in approximately 160 ticks

- If there are no threads in a given level, schedule threads from the next available level

- Thread level starts at 0 and can only increase throughout its lifetime
Priority Changing

- Threads are scheduled to run for the max duration of the current level
  - For example, in level 1, each thread will be scheduled to run for 2 quanta

- A thread is demoted if it uses up the entire quanta
  - What if the thread is from a different level?
Alarms

- Useful construct for scheduling a thread for future execution
  - Can be used for minithread_sleep()
- Each alarms requires a call back function
  - Call back functions might not be executed by the thread that registered the alarm!
- How to keep track of alarms?
  - Add functionality to existing queue.
  - Insert should be $O(n)$, remove min should be $O(1)$. 
Alarm Firing

- Where should the alarm be fired?
  - Interrupt handler

- When should an alarm be fired?
  - Tick == alarm expiration time
  - Can this be missed?

- How should the alarm be fired?
  - Context switch to alarm thread?
  - Should fire in the context of the currently executing thread
Testing

- There are a lot of parts to this project
  - Multi-level queue
  - Interrupts
  - Alarms
  - Thread levels

- Common pitfalls
  - Unnecessarily disabling interrupts
  - Not disabling interrupts when necessary
  - Multi-level queue corner cases
All library calls are safe: interrupts are automatically disabled upon calling

- interrupts will be restored to its original state (enabled/disabled) after the call.

Units of time

- PERIOD is defined as 50 ms, which is 50000 as a constant.
  - Alarm and wakeup delays are specified in milliseconds.
  - You have to convert units; don’t blindly subtract PERIOD.

Irregular/random clock interrupts

- This is normal
- Be careful of introducing heisenbugs because of your debug statements.
