Networking

CS 4410
Operating Systems

[R. Agarwal, L. Alvisi, A. Bracy, M. George, Kurose, Ross, E. Sirer, R. Van Renesse]
Introduction
Application Layer
Transport Layer
Network Layer
Remote Procedure Calls
Basic Network Abstraction

• A process can create “endpoints”
• Each endpoint has a unique address
• A message is a byte array
• Processes can:
  • receive messages on endpoints
  • send messages to endpoints
Network “protocol”

Agreement between processes about the content of messages

**Syntax:** Layout of bits, bytes, fields, etc.
  - message format

**Semantics:** what fields, messages mean

Example:

- HTTP “get” requests and responses
Network Layering

Network abstraction is usually *layered*
- Like Object Oriented-style inheritance
- Also like the hw/sw stack

### Proposed 7-Layer ISO/OSI Reference Model
- Application
- Presentation
- Session
- Transport
- Network
- Link
- Physical

### Actual 5-Layer Internet Protocol Stack
- Application
- Transport
- Network
- Link
- Physical
## OSI Layers

(Hard to draw firm lines here)

- Each host has 1+ Network Interface Cards (NIC)
- Attaches into host’s system buses
- Combination of hardware, software, firmware
Layers support **Modularity**

Each layer:
- relies on services from layer below
- exports services to layer above

Can identify the relationship between distinct pieces of complex system.

Interfaces between layers:
- Hide implementation details
- Ease maintenance, updates
  - change of implementation of layer’s service transparent to rest of system
Internet, The Big Picture

How about an analogy?
The Big Picture

Application

Transport

Network

Data Link

Physical

- **messages** from Application to Transport
- **segments** from Transport to Network
- **datagrams** or packets from Network to Data Link
- **frames** from Data Link to Physical
- **bits** from Physical to Application

Ports: (http: 80, DNS: 53, Telnet: 23)

IP addresses: (192.168.100.254)

MAC Addresses: (00:12:F4:AB:OC:82)
The Big Picture

Application ➔ messages ➔ Transport ➔ segments ➔ Network ➔ datagrams ➔ Data Link ➔ frames ➔ Physical ➔ bits ➔ Physical ➔ frames ➔ Data Link ➔ datagrams ➔ Network ➔ segments ➔ Transport ➔ messages ➔ Application
Encapsulation

Headers
- Transport: src & dst ports + ...
- Network: src & dest IP addr + ...
- Link: src & dest MAC addr + ...

source
- message
  - segment
  - datagram
  - frame

destination
- application
  - transport
  - network
  - link
  - physical

router
End-to-End Argument

• Occam’s Razor for Internet architecture
• Application-specific properties are best provided by the applications, not the network
  – Guaranteed, or ordered, packet delivery, duplicate suppression, security, etc.

• Internet performs the simplest packet routing and delivery service it can
  – Packets are sent on a best-effort basis
  – Higher-level applications do the rest
End-to-End Example

Should the network guarantee packet delivery?

Consider: a file transfer program (read file from disk, send it, receiver reads packets & writes them to disk)

- Q: If network guarantees delivery, wouldn’t applications be simpler? (no retransmissions!)
- A: no, still need to check that file was written to remote disk intact

A check is necessary if nodes can fail.

→ Applications need to be written to perform their own retransmits

*Why burden the network with properties that can, and must, be implemented at the periphery?*
Some issues...

• How do endpoints find each other?
• What does a message look like?
• Can messages be lost? large? jumbled?
The Missing Layers

**Presentation**
translation between network & application formats (e.g., RPC packages, sockets). Allows communicating applications to interpret the meaning of data exchanged:
- data conversion
- character code translation
- compression
- encryption

**Session**
synchronization of data exchange:
- supports checkpointing and recovery schemes
- establish, manage, and tear down connections

*Need these services? Put them in your application.*
Application Layer

Several figures in this section come from “Computer Networking: A Top Down Approach” by Jim Kurose, Keith Ross
Internet Overview

• Every **host** is assigned, and identified by, an **IP address**
• Each packet contains a header that specifies the destination address
• The network routes the packets from the source to the destination
People
• SSN, NetID, Passport #

Internet Hosts, Routers
1. IP address (32 bit), 151.101.117.67
   - For now, 32-bit descriptor, like a phone number
   - Longer addresses in the works…
   - Assigned to hosts by their internet service providers
   - **Not physical:** does not identify a single node, can swap machines and reuse the same IP address
   - **Not entirely virtual:** determines how packets get to you, changes when you change your ISP

2. Virtual: “name” www.cnn.com
   - Used by humans (no one wants to remember a bunch of #s)

How to convert hostname to IP address?
Domain Name System (DNS)

Distributed, Hierarchical Database

• Application-Layer Protocol: hosts & name servers communicate to resolve names
• Names are separated by dots into components
  Not to be confused with dots in IP addresses (in which the order of least significant to most significant is reversed)
• Components resolved from right to left
• All siblings must have unique names
• Lookup occurs from the top down
DNS: root name servers

Contacted by local name server that cannot resolve name
- owned by Internet Corporation for Assigned Names & Numbers (ICANN)
- contacts authoritative name server if name mapping not known
- gets mapping
- returns mapping to local name server

a. Verisign, Los Angeles CA (5 other sites)
b. USC-ISI Marina del Rey, CA
l. ICANN Los Angeles, CA (41 other sites)
c. Cogent, Herndon, VA (5 other sites)
d. U Maryland College Park, MD
h. ARL Aberdeen, MD
j. Verisign, Dulles VA (69 other sites )
e. NASA Mt View, CA
f. Internet Software C. Palo Alto, CA (and 48 other sites)
g. US DoD Columbus, OH (5 other sites)
h. ARL Aberdeen, MD
i. Netnod, Stockholm (37 other sites)
k. RIPE London (17 other sites)
l. WIDE Tokyo (5 other sites)

13 root name “servers” worldwide
DNS Lookup

1. the client asks its local nameserver
2. the local nameserver asks one of the root nameservers
3. the root nameserver replies with the address of the authoritative nameserver
4. the server then queries that nameserver
5. repeat until host is reached, cache result.

Example: Client wants IP addr of www.amazon.com

1. Queries root server to find com DNS server
2. Queries .com DNS server to get amazon.com DNS server
3. Queries amazon.com DNS server to get IP address for www.amazon.com
DNS Services

Simple, hierarchical namespace works well
- Can name anything
- Can alias hosts
- Can cache results
- Can share names (replicate web servers by having 1 name correspond to many IP addresses)

Q: Why not centralize?
- Single point of failure
- Traffic volume
- Distant Centralized Database
- Maintenance

A: Does not scale!
What about security? (don’t ask!)
Application Layer

• Network-aware applications
• Clients & Servers
• Peer-to-Peer
Sockets

“Door” between application process and end-end-transport protocol

Sending process:
• shoves message out door
• relies on transport infrastructure on other side of door to deliver message to socket at receiving process
Socket programming

Two socket types for two transport services:
• UDP: unreliable datagram
• TCP: reliable, byte stream-oriented

Host could be running many network applications at once. Distinguish them by binding the socket to a port number:
• 16 bit unsigned number
• 0-1023 are well-known
  (web server = 80, mail = 25, telnet = 23)
• the rest are up for grabs (see A3)
Application Example

1. Client reads a line of characters (data) from its keyboard and sends data to server
2. Server receives the data and converts characters to uppercase
3. Server sends modified data to client
4. Client receives modified data and displays line on its screen
Socket programming with UDP

No “connection” between client & server
• no handshaking before sending data
• **Sender**: explicitly attaches destination IP address & port # to each packet
• **Receiver**: extracts sender IP address and port # from received packet

Data may be lost, received out-of-order

Application viewpoint: UDP provides unreliable transfer of groups of bytes (“datagrams”) between client and server
Client/server socket interaction: UDP

**Server** (running on serverIP)  **Client**

create serversocket, bind to port x  create clientsocket  
create message

send message to (serverIP, port x) via clientsocket

read data (and clientAddr) from serversocket

modify data

send modified data to clientAddr via serversocket

receive message (and serverAddr) from clientsocket

close clientsocket
Python UDP Client

```python
import socket         # include Python's socket library
serverName = 'servername'
serverPort = 12000

# create UDP socket
clientSocket = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# get user input
message = input('Input lowercase sentence: 

# send with server name + port
clientSocket.sendto(message.encode(), (serverName, serverPort))

# get reply from socket and print it
modifiedMessage, serverAddress = clientSocket.recvfrom(2048)
print(modifiedMessage.decode())

clientSocket.close()```
import socket  # include Python’s socket library
serverPort = 12000

# create UDP socket & bind to local port 12000
serverSocket = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
serverSocket.bind(('', serverPort))
print("The server is ready to receive")

while True:
    # Read from serverSocket into message,
    # getting client’s address (client IP and port)
    message, clientAddress = serverSocket.recvfrom(2048)
    print(“received message: “+message.decode())

    modifiedMsg = message.decode().upper()
    print("sending back to client")

    # send uppercase string back to client
    serverSocket.sendto(modifiedMsg.encode(), clientAddress)
Socket programming w/ TCP

Client must contact server

Server:
- already running
- server already created
  “welcoming socket”

Client:
- Creates TCP socket w/ IP address, port # of server
- Client TCP establishes connection to server TCP

• when contacted by client, server TCP creates new socket to communicate with that particular client
  • allows server to talk with multiple clients
  • source port #s used to distinguish clients

Application viewpoint: TCP provides reliable, in-order byte-stream transfer between client & server
Client/server socket interaction: TCP

**Server** (running on `hostID`)

- create welcoming `serversocket`
- bind to `port x`

- in response to connection request,
  - create `connectionsocket`

- read data from `connectionsocket`
- modify data
- send modified data to `clientAddr`
  - via `connectionsocket`
- close `connectionsocket`

**Client**

- create `clientsocket`
- connect to `(hostID, port x)`
- create message
- send message via `clientsocket`
- receive message from `clientsocket`
- close `clientsocket`
import socket  # include Python’s socket library
serverName = ‘servername’
serverPort = 12000

# create TCP socket for server on port 12000
clientSocket = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
clientSocket.connect((serverName, serverPort))

# get user input
message = input('Input lowercase sentence: ‘

# send (no need for server name + port)
clientSocket.send(message.encode())

# get reply from socket and print it
modifiedMessage, serverAddress = clientSocket.recvfrom(1024)
print(modifiedMessage.decode())

clientSocket.close()
Python TCP Server

```python
ingo import socket  # include Python’s socket library
serverPort = 12000

# create TCP welcoming socket & bind to server port 12000
serverSocket = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
serverSocket.bind(('', serverPort))
# server begins listening for incoming TCP requests
serverSocket.listen(1)
print("The server is ready to receive")

while True:
    # server waits on accept() for incoming requests
    # new socket created on return
    connectionSocket, addr = serverSocket.accept()
    message = connectionSocket.recv(1024).decode()
    print("received message: "+message)
    modifiedMsg = message.upper()

    # send uppercase string back to client
    connectionSocket.send(modifiedMsg.encode())

    # close connection to this client, but not welcoming socket
    connectionSocket.close()
```
Transport Layer: UDP & TCP

Several figures in this section come from “Computer Networking: A Top Down Approach” by Jim Kurose, Keith Ross
Transport services and protocols

- Provide **logical** communication between processes on different hosts
- Run in end systems
  - **Sender**: packages messages into segments, passes to network layer
  - **Receiver**: reassembles segments into messages, passes to application layer

App chooses protocol it wants (e.g., TCP or UDP)
Transport services and protocols

User Datagram Protocol (UDP)
- unreliable, unordered delivery
- no-frills extension of best-effort IP

Transmission Control Protocol (TCP)
- reliable, in-order delivery
- congestion control
- flow control
- connection setup

Services not available:
- delay guarantees
- bandwidth guarantees
Transport Layer Analogy

2 houses (hosts), each has 12 kid siblings

Kids: (applications)
  • write letters (messages) to cousins

Parents: (transport layer protocol)
  • gather the letters (multiplexing)
  • put them in addressed envelopes (segments)
  • give them to the postman (network layer)
  • get letters from postman, deliver (demux) to kids
How to create a **segment**

**Sending application:**
- specifies **IP address** and destination port
- uses socket bound to a source port

**Transport Layer:**
- breaks **application message** into smaller chunks
- adds transport-layer header to each

**Network Layer:**
- adds network-layer header (with IP address)
Multiplexing at Sender

- handles data from multiple sockets
- adds transport header (later used for demultiplexing)
Demultiplexing at Receiver

- use header information to deliver received segments to correct socket

**sources**

- application
- transport
- network
- link
- physical

**destination**

- application
- transport
- network
- link
- physical

**sources**

- server: IP address
- transport
- network
- link
- physical

**host: IP address**

- A
- B
- C
- D

<table>
<thead>
<tr>
<th>src</th>
<th>dst</th>
</tr>
</thead>
<tbody>
<tr>
<td>9157</td>
<td>80</td>
</tr>
<tr>
<td>5775</td>
<td>53</td>
</tr>
</tbody>
</table>
User Datagram Protocol (UDP)

- no frills, bare bones transport protocol
- **best effort** service, UDP segments may be:
  - lost
  - delivered out-of-order, duplicated to app
- **connectionless**:
  - no handshaking between UDP sender, receiver
  - each UDP segment handled independently of others
- reliable transfer still possible:
  - **add reliability at application layer**
  - application-specific error recovery!

---

I was gonna tell you guys a joke about UDP…
But you might not get it

I was you guys about UDP might not
Connectionless demux: example

Host receives 2 UDP segments:

- checks **dst port**, directs segment to socket w/that port
- different **src IP or port** but same **dst port** → **same socket**
- application must sort it out

Host: IP address A

**sources**

application

transport

network

link

physical

**P3**

9157

**P1**

6428

**s**: 9157 | 6428

**d**: B

**src** | **dst**

9157 | 6428

**server:** IP address B

**sources**

application

transport

network

link

**P4**

5775

**s**: 5785 | 6428

**d**: B

**src** | **dst**

5785 | 6428

**host:** IP address C

application

transport

network

link

physical

**host:** IP address C
UDP Segment Format

length (in bytes) of UDP segment, including header

UDP header size: 8 bytes

(IP address will be added when the segment is turned into a datagram/packet at the Network layer)
UDP Advantages & Disadvantages

**Speed:**
- no connection establishment (which can add delay)
- no congestion control: UDP can blast away as fast as desired

**Simplicity:**
- no connection state at sender, receiver
- small header size (8 bytes)

(Possibly) **Extra work for applications:**
Need to handle reordering, duplicate suppression, missing packets

*Not all applications will care about these!*
Who uses UDP?

**Target Users:** streaming multimedia apps

- loss tolerant *(occasional packet drop OK)*
- rate sensitive *(want constant, fast speeds)*

UDP is good to build on
## Applications & their transport protocols

</tr>
</tbody>
</table>
Transmission Control Protocol (TCP)

• Reliable, ordered communication
• Standard, adaptive protocol that delivers good-enough performance and deals well with congestion
• All web traffic travels over TCP/IP

• Why? Enough applications demand reliable ordered delivery that they should not have to implement their own protocol
TCP Segment Format

HL: header len

U: urgent data

A: ACK # valid

P: push data now

RST, SYN, FIN: connection commands (setup, teardown)

# bytes receiver willing to accept

TCP header size: 20-60 bytes

(IP address will be added when the segment is turned into a datagram/packet at the Network)
TCP Connections

- TCP is *connection* oriented
- A connection is initiated with a three-way handshake
- Three-way handshake ensures against duplicate SYN packets
- Takes 3 packets, 1.5 RTT (Round Trip Time)

**SYN** = Synchronize
**ACK** = Acknowledgment

*I would tell you a joke about TCP... If only to be acknowledged 😞*
TCP Handshakes

3-way handshake establishes common state on both sides of a connection.
Both sides will:

• have seen one packet from the other side → know what the first seq# ought to be
• know that the other side is ready to receive

Server will typically create a new socket for the client upon connection.
TCP Sockets

Server host may support many simultaneous TCP sockets
Each socket identified by its own 4-tuple

- source IP address
- source port number
- dest IP address
- dest port number

Connection-oriented demux: receiver uses all 4 values to direct segment to appropriate socket
Connection-oriented demux: example

Host receives 3 TCP segments:
- all destined to **IP addr B, port 80**
- demuxed to different sockets with socket’s 4-tuple

TCP Packets

Each packet carries a unique sequence #

• The initial number is chosen randomly
• The SEQ is incremented by the data length

4410 simplification: just increment by 1

Each packet carries an acknowledgment

• Acknowledge a set of packets by ACK-ing the latest SEQ received

Reliable transport is implemented using these identifiers
TCP Usage Pattern

3 round-trips:
1. set up a connection
2. send data & receive a response
3. tear down connection

FINs work (mostly) like SYNs to tear down connection

Need to wait after a FIN for straggling packets
Reliable transport

- Sender-side: TCP keeps a copy of all sent, but unacknowledged packets
- If acknowledgment does not arrive within a “send timeout” period, packet is resent
- Send timeout adjusts to the round-trip delay

Here's a joke about TCP. Did you get it? Did you get it? Did you get it? Did you get it?
How long does it take to send a segment?

- S: size of segment in bytes
- L: one-way latency in seconds
- B: bandwidth in bytes per second

Then the time between the start of sending and the completion of receiving is about \( L + \frac{S}{B} \) seconds (ignoring headers)

- And another L seconds (total: \( 2L + \frac{S}{B} \)) before the acknowledgment is received by the sender
  - assuming ack segments are small

- The resulting end-to-end throughput (without pipelining) would be about \( \frac{S}{2L + \frac{S}{B}} \) bytes/second
TCP timeouts

What is a good timeout period?
- Goal: improve throughput without unnecessary transmissions

NewAverageRTT = \((1 - \alpha)\) OldAverageRTT + \(\alpha\) LatestRTT
NewAverageVar = \((1 - \beta)\) OldAverageVar + \(\beta\) LatestVar

where LatestRTT = (ack_receive_time - send_time),
    LatestVar = |LatestRTT - AverageRTT|,
    \(\alpha = 1/8, \beta = \frac{1}{4}\) typically.

Timeout = AverageRTT + 4*AverageVar

→ Timeout is a function of RTT and variance
Pipelined Protocols

Pipelining: sender allows multiple, “in-flight”, yet-to-be-acknowledged packets
• increases throughput
• need buffering at sender and receiver
• How big should the window be?
• What if a packet in the middle goes missing?

![Diagram of data packets and acknowledgments](image)
Example: TCP Window Size = 4

When first item in window is acknowledged, sender can send the 5th item.
How much data “fits” in a pipe?

Suppose:
• b/w is $b$ bytes / second
• RTT is $r$ seconds
• ACK is a small message

→ you can send $b \times r$ bytes before receiving an ACK for the first byte

(but b/w and RTT are both variable…)
Receiver detects a lost packet (i.e., a missing seq), ACKs the last id it successfully received.

Sender can detect the loss without waiting for timeout.
TCP Fast Retransmit

Receiver detects a lost packet (i.e., a missing seq), ACKs the last id it successfully received.

Sender can detect the loss without waiting for timeout.
TCP Congestion Control

Additive-Increase/Multiplicative-Decrease (AIMD):

- window size++ every RTT if no packets dropped
- window size/2 if packet is dropped
  - drop evident from the acknowledgments

→ slowly builds up to max bandwidth, and hover there
  - Does not achieve the max possible
  + Shares bandwidth well with other TCP connections

This linear-increase, exponential backoff in the face of congestion is termed **TCP-friendliness**
TCP Window Size

- Linear increase
- Exponential backoff

( Assuming no other losses in the network except those due to bandwidth)

Window Sizes: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 5, 6, 7, 8, 9, 10, ...

Max Bandwidth

Bandwidth

Time
TCP Fairness

**Fairness goal:** if $k$ TCP sessions share the same bottleneck link of bandwidth $R$, each should have average rate of $R/k$
Why is TCP fair?

Two competing sessions:
- additive increase gives slope of 1, as throughput increases
- multiplicative decrease decreases throughput proportionally

Connection 1 throughput  
Connection 2 throughput

equal bandwidth share

loss: decrease window by factor of 2

congestion avoidance: additive increase
decrease window by factor of 2
congestion avoidance: additive increase
Problem:
- Linear increase takes a long time to build up a window size that matches the link bandwidth*delay
- Most file transactions are short
  → TCP spends a lot of time with small windows, never reaching large window size

Solution: Allow TCP to increase window size by doubling until first loss

Initial rate is slow but ramps up exponentially fast
TCP Slow Start

- Initial phase: **exponential increase**
- Assuming no other losses in the network except those due to bandwidth
TCP Summary

• Reliable ordered message delivery
  – Connection oriented, 3-way handshake

• Transmission window for better throughput
  – Timeouts based on link parameters

• Congestion control
  – Linear increase, exponential backoff

• Fast adaptation
  – Exponential increase in the initial phase
Link Layer: Local Area Networking (LAN) and Ethernet
Link Layer

• Each host has one or more NICs
  • *Network Interface Cards*
    – Ethernet, 802.11, etc.
• Each NIC has a *MAC address*
  • *Media Access Control* address
  • Ethernet example: b8:e3:56:15:6a:72
  • Unique to network instance
    – often even globally unique
• Messages are *packets* or *frames*
Example: Ethernet

• 1976, Metcalfe & Boggs at Xerox
  – Later at 3COM
• Based on the Aloha network in Hawaii
• Named after the “luminiferous ether”
• Centered around a broadcast bus
• Simple link-level protocol, scales pretty well
• Tremendously successful
• Still in widespread use
  – many orders of magnitude increase in bandwidth since early versions
### Ethernet basics

#### An Ethernet packet

<table>
<thead>
<tr>

<tr>
<td>Checksum</td>
</tr>
</tbody>
</table>

header
“CSMA/CD”

- **Carrier sense**
  - Listen before you speak
- **Multiple access**
  - Multiple hosts can access the network
- **Collision detect**
  - Detect and respond to cases where two hosts collide
Sending packets

- Carrier sense, broadcast if ether is available
Collisions

- What happens if two people decide to transmit simultaneously?
Collision Detection & Retransmission

• The hosts involved in the collision stop data transmission, sleep for a while, and attempt to retransmit
• How long they sleep is determined by how many collisions have occurred before
• They abort after 16 retries, hence no guarantee that a packet will get to its destination
CRC Checksum
(Cyclic Redundancy Check)

• Basically a hash function on the packet
• Added to the end of a packet
• Used to detect malformed packets, e.g. electrical interference, noise
Ethernet Features

• Completely distributed
  – No central arbiter

• Inexpensive
  – No state in the network
  – No arbiter
  – Cheap physical links (twisted pair of wires)
Ethernet Problems

• The endpoints are trusted to follow the collision-detect and retransmit protocol
  – Certification process tries to assure compliance
  – Not everyone always backs off exponentially

• Hosts are trusted to only listen to packets destined for them
  – But the data is available for all to see
    • All packets are broadcast on the wire
    • Can place Ethernet card in promiscuous mode and listen
Switched Ethernet

• Today’s Ethernet deployments are much faster
• In wired settings, *Switched Ethernet* has become the norm
  • All hosts connect to a switch
  • Each p2p connection is a mini Ethernet set-up
  • More secure, no possibility of snooping
  • Switches organize into a spanning tree

• Not to be confused with Ethernet *Hub*
  • A hub simply connects the wires
Wireless

• 802.11 protocols inherit many of the Ethernet concepts
• Full compatibility with Ethernet interface
  • Same address and packet formats
Lessons for LAN design

- Best-effort delivery simplifies network design
- A simple, distributed protocol can tolerate failures and be easy to administer

Network Layer
Network Layer

• There are lots of Local Area Networks
  • each with their own
    – address format and allocation scheme
    – packet format
    – LAN-level protocols, reliability guarantees

• Wouldn’t it be nice to tie them all together?
  • Nodes with multiple NICs can provide the glue!
  • Standardize address and packet formats

• This gives rise to an “Internetwork”
  • aka WAN (wide-area network)
Internetworking Origins

- Expensive supercomputers scattered throughout the US
- Researchers scattered differently throughout the US
- Needed a way to connect researchers to expensive machinery
Internetworking Origins

• Department of Defense initiated studies on how to build a resilient global network (60s, 70s)
  – How do you coordinate a nuclear attack?
• Interoperability and dynamic routing are a must
  – Along with a lot of other properties
• Result: Internet (orig. ARPAnet, then NSFnet)
• A complex system with simple components
Internet Overview

• Every host is assigned, and identified by, an **IP address**
• Messages are called **datagrams**
  • the term *packet* is probably more common though…
• Each datagram contains a **header** that specifies the destination address
• The network **routes** datagrams from the source to the destination
IP

• Internetworking protocol
  – Network layer
• Common address format
• Common packet format for the Internet
  – Specifies what packets look like
  – *Fragments* long packets into shorter packets
  – *Reassembles* fragments into original shape

• IPv4 vs IPv6
  – IPv4 is what most people use
  – IPv6 more scalable and clears up some of the messy parts
IP: Narrow Waist

from: http://if-we.clients.labzero.com/code/posts/what-title-ii-means-for-tcp/
IP Addressing

• Every (active) NIC has an IP address
  – IPv4: 32-bit descriptor, e.g. 128.84.12.43
  – IPv6: 128-bit descriptor (but only 64 bits “functional”)
    – Will use IPv4 unless specified otherwise…

• Each Internet Service Provider (ISP) owns a set of IP addresses
• ISPs assign IP addresses to NICs
• IP addresses can be re-used
• Same NIC may have different IP addresses over time
IP “subnetting”

• An IP address consists of a prefix of size $n$ and a suffix of size $32 - n$
  • Either specified by a number, e.g., 128.84.32.00/24
  • Or a “netmask”, e.g., 255.255.255.0 (in case $n = 24$)
• A “subnet” is identified by a prefix and has $2^{32-n}$ addresses
  • Suffix of “all zeroes” or “all ones” reserved for broadcast
  • Big subnets have a short prefix and a long suffix
  • Small subnets have a long prefix and a short suffix
DHCP is used to discover IP addresses (and more)

DHCP = Dynamic Host Configuration Protocol
DHCP

- Each LAN (usually) runs a DHCP server
  - you probably run one at home inside your “router box”
- DHCP server maintains
  - the IP subnet that it owns (say, 128.84.245.00/24)
  - a map of IP address <-> MAC address
    - possibly with a timeout (called a “lease”)
- When a NIC comes up, it broadcasts a DHCPDISCOVER message
  - if MAC address in the map, respond with corresponding IP address
  - if not, but an IP address is unmapped and thus available, map that IP address and respond with that
- DHCP also returns the netmask
- Note: NICs can also be statically configured and don’t need DHCP
Addressing & ARP

- ARP is used to discover MAC addresses on same subnet
  - ARP = Address Resolution Protocol

"What is the physical address of the host named 128.84.96.89"

"I’m at 1a:34:2c:9a:de:cc"
Scale?

• ARP and DHCP only scale to single subnet
• Need more to scale to the Internet!
### IPv4 packet layout

<table>
<thead>
<tr>

<td>Payload</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
IP Header Fields

- Version (4 bits): 4 or 6
- IHL (4 bits): Internet Header Length in 32-bit words
  - usually 5 unless options are present
- TOS (1 byte): type of service (not used much)
- Total Length (2 bytes): length of packet in bytes
- Id (2 bytes), Flags (3 bits), Fragment Offset (13 bits)
  - used for fragmentation/reassembly. Stay tuned
- TTL (1 byte): Time To Live. Decremented at each hop
- Protocol (1 byte): TCP, UDP, ICMP, …
- Header Checksum (2 bytes): to detect corrupted headers
IP Fragmentation

• Networks have different maximum packet sizes
  • “MTU”: Maximum Transmission Unit
    – Big packets are sometimes desirable – less overhead
    – Huge packets are not desirable – reduced response time for others
• High-level protocols could try to figure out the minimum MTU along the network path, but
  – Inefficient for links with large MTUs
  – The route can change underneath
• Consequently, IP can transparently fragment and reassemble packets
IP Fragmentation Mechanics

- Source assigns each datagram an “identification”
- At each hop, IP can divide a long datagram into N smaller datagrams
- Sets the More Fragments bit except on the last packet
- Receiving end puts the fragments together based on Identification and More Fragments and Fragment Offset (times 8)
IP Options (not well supported)

- Source Routing: The source specifies the set of hosts that the packet should traverse
- Record Route: If this option appears in a packet, every router along a path attaches its own IP address to the packet
- Timestamp: Every router along the route attaches a timestamp to the packet
- Security: Packets are marked with user info, and the security classification of the person on whose behalf they travel on the network
  - Most of these options pose security holes and are generally not implemented
Routing
The Internet is Big...
Routing

• How do we route messages from one machine to another?
• Subject to
  – churn
  – efficiency
  – reliability
  – economical considerations
  – political considerations
Internet Protocol (IP)

- The Internet is subdivided into disjoint Autonomous Systems (AS)

Graph of subgraphs
Autonomous Systems

• Each AS is a routing domain in its own right
  • has a private IP network
  • runs its own routing protocols
  • may have multiple IP subnets
    – each with their own IP prefix
• has a unique “AS number”

• ASs are organized in a graph
  • routing between ASs using BGP (Border Gateway Protocol)
Thus routing is hierarchical!

Three steps:

1. A packet is first routed to an “edge router” at the source AS---using the internal routing protocol used by the source AS

2. Next the packet is routed to an edge router at the destination AS---determined by the destination address prefix---using BGP

3. The destination AS’s edge router then forwards the packet to its ultimate destination---determined by the address suffix---using the internal routing protocol used by the destination AS
Internet Routing, observations

• There are no longer special “government” routers that route between ASs. Instead, each AS has one or more “edge routers” that are connected by interdomain links.

• Two types:
  • **Transit AS**: forwards packets coming from one AS to another AS
  • **Stub AS**: has only “upstream” links and does not do any forwarding
What’s an ISP?

• An ISP (Internet Service Provider) is simply an AS (or collection of ASs) that provides, to its customers (which may be people or other ASs), access to the “The Internet”

• Provides one or more PoPs (Points of Presence) for its customers.
Routers (Layer-3 Switches)

• Connects multiple LANs (subnets)

• Two classes:
  • Edge or Border router: Resides at the edge of an AS, and has two faces
    – one faces outside to connect to one or more per edge router in other ASs
    – one faces inside, connecting to zero or more other routers within the same AS

• Interior router:
  – has no connections to routers in other ASs
Routing Table

- Maps IP address to interface or port and to MAC address
- Longest Prefix Matching
- Your laptop/phone has a routing table too!

<table>
<thead>
<tr>
<th>Address</th>
<th>IF or Port</th>
<th>MAC</th>
</tr>
</thead>
<tbody>
<tr>
<td>128.84.216/23</td>
<td>en0</td>
<td>c4:2c:03:28:a1:39</td>
</tr>
<tr>
<td>127/8</td>
<td>lo0</td>
<td>127.0.0.1</td>
</tr>
<tr>
<td>128.84.216.36/32</td>
<td>en0</td>
<td>74:ea:3a:ef:60:03</td>
</tr>
<tr>
<td>128.84.216.80/32</td>
<td>en0</td>
<td>20:aa:4b:38:03:24</td>
</tr>
<tr>
<td>128.84.217.255/32</td>
<td>en0</td>
<td>ff:ff:ff:ff:ff:ff</td>
</tr>
</tbody>
</table>
Router Function

often implemented in hardware

for ever:

receive IP packet $p$

if isLocal($p$.dest): return localDelivery($p$)

if --$p$.TTL == 0: return dropPacket($p$)

matches = {}

for each entry $e$ in routing table:

    if $p$.dest & $e$.netmask == $e$.address & $e$.netmask:
        matches.add($e$)

bestmatch = matches.maxarg($e$.netmask)

forward $p$ to bestmatch.port/bestmatch.MAC
Routing Loops?

- In steady state, there should be no routing loops.
- But steady state is rare. If routing tables are not in sync, routing loops can occur.
- To avoid problems, IP packets maintain a maximum hop count (TTL) that is decreased on every hop until 0 is reached, at which point a packet is dropped.
How are these routing tables constructed?

• For end-hosts, mostly DHCP and ARP as discussed before
• For routers, using a “routing protocol”
  • take Prof. Agarwal’s networking course!
Network Address Translation

- IPv6 adoption is very slow, and IPv4 addresses have run out
- NAT allows entire sites to use a single globally routable IPv4 address for a collection of machines
  - exploits the sparsely used 16-bit TCP/UDP port number space
- A “NAT box” keeps a table that maps global TCP/IP addresses into local ones
- Overwrites the local source address with the globally addressable address
“Private” IP addresses

• The IPv4 addresses 10.x.x.x and 192.168.x.x are freely available for anybody to use

• Many machines have the IP address 192.168.0.100, for example
From your laptop to Google…

NIC (your laptop)
192.168.1.100

NIC (Google)
74.125.141.147

Internet

NAT

dst: 74.125.141.147:80
csrc: 192.168.1.100:4410

NIC
192.168.1.1

NIC
128.84.34.124

dst: 74.125.141.147:80
csrc: 128.84.34.124:123
Vice versa: punching holes or “game ports”

• When an external host tries to send a message to one of your machines in your house, it first arrives at the NAT box
• Because you advertise your global IP address
• How does the NAT box know which of your machines to forward the message to?
• Answer: a table. It is indexed by the destination TCP or UDP port in the message
Remote Procedure Call

Several figures in this section come from “Distributed Systems: Principles and Paradigms” by Andrew Tanenbaum & Maarten van Steen
Client/Server Paradigm

Common model for structuring distributed computation

- **Server:** program (or collection of programs) that provide some service, e.g., file service, name service
  - may exist on one or more nodes
- **Client:** a program that uses the service

**Typical Pattern:**
1. Client first *connects* to the server: locates it in the network & establishes a connection
2. Client sends *requests*: messages that indicate which service is desired and the parameters
3. Server returns *response*
Pros and Cons of Messages

+ Very flexible communication
  • Want a certain message format? Go for it!

− Problems with messages:
  • programmer must worry about message formats
  • must be packed and unpacked
  • server must decode to determined request
  • may require special error handling functions
Procedure Call

A more natural way to communicate:
- every language supports it
- semantics are well defined and understood
- natural for programmers to use

Idea: Let clients call servers like they do procedures
Remote Procedure Call (RPC)

**Goal:** design RPC to look like a local PC
- A model for distributed communication
- Uses computer/language support
- 3 components on each side:
  - user program (client or server)
  - set of *stub* procedures
  - RPC runtime support

*Birrell & Nelson @ Xerox PARC*  
How does a function call work?

read(int fd, char* buf, int nbytes)

- File descriptor
- Character array
- How much to read

- Linker inserts read implementation into obj file
- Implementation usually invokes a system call

[Tanenbaum & van Steen, Fig]
How does a RPC work?

Basic idea:
• Server *exports* a set of procedures
• Client calls these procedures, as if they were local functions

![Diagram showing the process of a RPC call](image)

- Message passing details hidden from client & server (like system call details are hidden in libraries)

[Tanenbaum & van Steen, Fig 4-6]
RPC Stubs

Client-side stub:
- Looks (to the client) like a callable server procedure
- Client program thinks it is calling the server

Server-side stub:
- Server program thinks it is called by the client
- `foo` actually called by the server stub

Stubs send messages to each other to make RPC happen
RPC Call Structure

1. Client program calls `foo(x,y)`
2. Client stub builds msg, calls OS
3. RPC runtime sends msg to remote node
4. Server stub receives msg, calls
5. Unpacks params, makes call
6. Server program begins `foo(a,b)`

Call
RPC Return Structure

1. The client program calls `foo(x,y)`.
2. The server program begins the `foo` procedure.
3. The client stub unpacks the message, returns result to stub.
4. The server stub receives the message, gives to stub.
5. The RPC runtime receives the message, gives to stub.
6. The client stub continues.
7. The server stub sends the message.
8. The client stub responds to original message.
Example RPC system: **Stub compiler**
- reads IDL
- produces 2 stub procedures for each server procedure:
  (1) client-side stub
  (2) a server-side stub
Example RPC system:

Server writer:
- writes server
- links it with server-side stubs
Binding: Connecting Client & Server

Server *exports* its interface:
- identifying itself to a network name server
- telling the local runtime its dispatcher address

Client *imports* the interface. RPC runtime:
- looks up the server through the name service
- contacts requested server to set up a connection

*Import* and *export* are explicit calls in the code

---

DCE = Distributed Computing Environment
RPC Concerns

- Parameter Passing
- Failure Cases
- Performance

Your function call has been secretly replaced with a remote function call. Is this okay?
RPC Marshaling

Packing parameters into a message packet

• RPC stubs call type-specific procedures to marshal (or unmarshal) all of the parameters to the call

On Call:

• **Client stub marshals** parameters into the call packet
• **Server stub unmarshals** parameters to call server’s fn

On return:

• **Server stub marshals** return values into return packet
• **Client stub unmarshals** return values, returns to client
Parameter Passing

What could go wrong?

[Tanenbaum & van Steen, Fig 4-7]
RPC Concerns

- Parameter Passing
  - Data Representation
- Passing Pointers
- Global Variables
- Failure Cases
- Performance
Data Representation

Data representation? ASCII vs. Unicode, structure alignment, n-bit machines, floating-point representations, endian-ness

Server program defines interface using an *interface definition language* (IDL)

For all client-callable functions, IDL specifies:
• names
• parameters
• types
Passing Pointers

- Forbid pointers? (breaks transparency)
- Have server call client and ask it to modify when needed (breaks transparency)
- Have stubs replace call-by-reference semantics with Copy/Restore
- Optimization: if stub knows that a reference is exclusively input/output copy only on call/return
- Only works for simple arrays & structures
  - Union types? YUCK
  - Multi-linked structures? YUCK
  - Raw pointers? YUCK
RPC Concerns

• Parameter Passing
• Failure Cases
• Performance
RPC Failure Cases

Function call failure cases:
• Called fn crashes → so does the caller

RPC Failure cases:
• server fine, client crashes? (orphans)
• client fine, server crashes?
  • Client just hangs?
  • Stub supports a timeout, error after n tries?
• Client deals w/failure (breaks transparency)
Aside: Idempotency
Multiple calls yields the same result

What’s idempotent?
• read block 50

What’s not?
• appending to a file
How many times will a function be executed?

A calls B. B never responds… Should A resend or not?

2 Possibilities:

(1) B never got the call:
• Resend → B executes the procedure once
• Don’t resend → B executes the procedure zero times

(2) B performed the call then crashed:
• Resend → B executes the procedure twice
• Don’t resend → B executes the procedure once

Can we even promise transparency?
What semantics will RPC support?

A calls B. B responds… What does A assume about how many times the function was executed?

Exactly once:
- system guarantees local semantics
- at best expensive, at worst, impossible

At-least-once:
+ easy: no response? A re-sends
- only works for idempotent functions
- server operations must be stateless

At-most-once:
- requires server to detect duplicate packets
+ works for non-idempotent functions
RPC Concerns

- Parameter Passing
- Failure Cases
- Performance
  - Remote is not cheap
  - Lack of parallelism (on both sides)
  - Lack of streaming (for passing data)
RPC Concluding Remarks

RPC:

- Common model for distributed application communication
- *language support* for distributed programming
- relies on a *stub compiler* & IDL server description
- commonly used, even on a *single node*, for communication between applications running in different address spaces (most RPCs *are* intra-node!)

“*Distributed objects are different from local objects, and keeping that difference visible will keep the programmer from forgetting the difference and making mistakes.*”

—Jim Waldo+, “A Note on Distributed Computing” (1994)
