## CS4450

# Computer Networks: Architecture and Protocols 

## Lecture 12

Distance Vector Routing

Spring 2018
Rachit Agarwal

## Announcements

- Problem Set 3 will be up soon (definitely by Saturday)
- During my first lecture, I promised you:
- I care about you(r learning)!
- If you stick to the contract, l'll bring my A game in every lecture!
- You have been great so far!
- I will stick to my promise
- We are almost half-way through
- If you think I am not bringing my A-game in the course
- I want to know and improve!!!
- Please fill out the mid-term evaluation (this weekend)
- Completely anonymized; only for my eyes; max 5 min

## Goals for Today's Lecture

- Distance Vector (Local view)
- Maintain sanity: its one of the "harder" lectures
- I'll try to make it -less- hard, but ...
- Pay attention
- Review again tomorrow
- Work out a few examples

## Recap: Four flavors of protocols

- Create Tree, route on tree
- E.g., Spanning tree protocol (switched Ethernet)
- Good: easy, no (persistent) loops, no dead ends
- Not-so-good: unnecessary processing, high latency, low bandwidth
- Obtain a global view:
- E.g., Link state (last lecture)
- Distributed route computation:
- E.g., Distance vector
- E.g., Border Gateway Protocol
- Today: Distributed route computation

## Recap: Spanning Tree Protocol

- Messages ( $\mathrm{Y}, \mathrm{d}, \mathrm{X}$ ): For root $Y$; From node $X$; advertising a distance $d$ to $Y$
- Initially each switch $X$ announces $(X, 0, X)$ to its neighbors
- Switches update their view
- Upon receiving message ( $\mathrm{Y}, \mathrm{d}, \mathrm{Y}$ ) from Z , check Y 's id
- If Y's id < current root: set root = Y
- Switches compute their distance from the root
- Add 1 to the shortest distance received from a neighbor
- If root changed OR shortest distance to the root changed, send all neighbors updated message ( $\mathrm{Y}, \mathrm{d}+1, \mathrm{X}$ )

## Distributed Route Computation

## Distributed Computation of Routes

- Each node computing the outgoing links based on:
- Local link costs
- Information advertised by neighbors
- Algorithms differ in what these exchanges contain
- Distance-vector: just the distance (and next hop) to each destination
- Path vector: the entire path to each destination
- We will focus on distance-vector for now

## Recall: Routing Tables = Collection of Spanning Trees

- Can we use the spanning tree protocol (with modifications)?
- Messages ( $\mathrm{Y}, \mathrm{d}, \mathrm{X}$ ): For root Y ; From node X ; advertising a distance d to Y
- Initially each switch $X$ announces $(X, 0, X)$ to its neighbors

## Towards Distance Vector Protocol (with no failures)

- Messages (Y,d,X): For root Y; From node X; advertising a distance d to Y
- Initially each switch X announces $(\mathrm{X}, 0, \mathrm{X})$ to its neighbors
- Switches update their view
- Upon receiving message ( $\mathrm{Y}, \mathrm{d}, \mathrm{Z}$ ) from Z ,check Y 's id
- If $Y^{\prime}$ s id < current root: set root destination $=Y$
- Switches compute their shortest distance from the root destination
- If current_distance_to_Y > d + cost of link to $X$ :
- update current_distance_to_Y = d
- If root changed OR shortest distance to the root destination changed, send all neighbors updated message ( $\mathrm{Y}, \mathrm{d}+\mathrm{c}, \mathrm{X}$ )

## Group Exercise:

## Lets run the Protocol on this example

## Round 1

## Round 2

|  | Receive | Send |
| :---: | :---: | :---: |
| $\begin{gathered} 1 \\ (1,0,1) \end{gathered}$ | $\begin{aligned} & (2,0,2), \\ & (3,0,3) \end{aligned}$ | $\begin{aligned} & (2,2,1) \\ & (3,1,1) \end{aligned}$ |
| $\begin{gathered} 2 \\ (2,0,2) \end{gathered}$ | $\begin{aligned} & (1,0,1), \\ & (3,0,3) \end{aligned}$ | $\begin{aligned} & (1,2,2), \\ & (3,7,2) \end{aligned}$ |
| $\begin{gathered} 3 \\ (3,0,3) \end{gathered}$ | $\begin{aligned} & (1,0,1), \\ & (2,0,2) \end{aligned}$ | $\begin{aligned} & (1,1,3), \\ & (2,7,3) \end{aligned}$ |

## Round 3

|  | Receive | Send |
| :---: | :---: | :---: |
| 1 | $(1,2,2)$, |  |
| $(1,0,1)$ | $(3,7,2)$, |  |
| $(2,2,1)$, | $(1,1,3)$, |  |
| $(3,1,1)$ | $(2,7,3)$ |  |
| 2 | $(2,2,1)$, |  |
| $(1,2,2)$, | $(3,1,1)$, | $(3,3,2)$ |
| $(2,0,2)$, | $(1,1,3)$, |  |
| $(3,7,2)$ | $(2,7,3)$ |  |
| 3 | $(2,2,1)$, |  |
| $(1,1,3)$, | $(3,1,1)$, | $(2,3,3)$ |
| $(2,7,3)$, | $(1,2,2)$, |  |
| $(3,0,3)$ | $(3,7,2)$ |  |
|  |  |  |

## Round 4

|  | Receive | Send |
| :---: | :---: | :---: |
| 1, |  |  |
| $(1,0,1)$ | $(3,3,2)$, |  |
| $(2,2,1)$, | $(2,3,3)$ |  |
| $(3,1,1)$ |  |  |
| 2 |  |  |
| $(1,2,2)$, <br> $(2,0,2)$, <br> $(3,3,2)$ | $(2,3,3)$ |  |
| 3 |  |  |
| $(1,1,3)$, <br> $(2,3,3)$, <br> $(3,0,3)$ | $(3,3,2)$ |  |

## Towards Distance-vector protocol with next-hops (no failures)

- Messages ( $\mathrm{Y}, \mathrm{d}, \mathrm{X}$ ): For root Y ; From node X ; advertising a distance d to Y
- Initially each switch X announces $(\mathrm{X}, 0, \mathrm{X})$ to its neighbors
- Switches update their view
- Upon receiving message ( $\mathrm{Y}, \mathrm{d}, \mathrm{Z}$ ) from $Z$,-check $\mathrm{Y}^{\prime}$ 'id
- If $Y^{\prime}$ s id < current root: set root destination $=Y$
- Switches compute their shortest distance from the root destination
- If current_distance_to_Y > d + cost of link to $X$ :
- update current_distance_to_Y = d
- update next_hop_to_destination = X
- If root changed OR shortest distance to the root destination changed, send all neighbors updated message ( $\mathrm{Y}, \mathrm{d}+\mathrm{c}, \mathrm{X}$ )

## Group Exercise:

## Lets run the Protocol on this example

## (this time with next-hops)

## Round 1

## Round 2

|  | Receive | Send | Next-hops |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
| 1 | $(2,0,2)$, | $(2,2,1)$, | $[-$, |
| $(1,0,1)$ | $(3,0,3)$ | $(3,1,1)$ | 2, |
|  |  |  | $3]$ |
|  | $(1,0,1)$, | $(1,2,2)$, | $[1$, |
|  | $(3,0,3)$ | $(3,7,2)$ | ,- |
|  |  |  | $3]$ |
|  | $(1,0,1)$, | $(1,1,3)$, | $[1$, |
| 3 | $(2,0,2)$ | $(2,7,3)$ | 2, |
| $(3,0,3)$ |  |  | $-]$ |

## Round 3

|  | Receive | Send | Next-hops |
| :---: | :---: | :---: | :---: |
| 1 | $(1,2,2)$, |  | $[-$, |
| $(1,0,1)$ | $(3,7,2)$, |  | 2, |
| $(2,2,1)$, | $(1,1,3)$, |  | $3]$ |
| $(3,1,1)$ | $(2,7,3)$ |  |  |
| 2 | $(2,2,1)$, |  | $[1$, |
| $(1,2,2)$, | $(3,1,1)$, | $(3,3,2)$ | ,- |
| $(2,0,2)$, | $(1,1,3)$, |  | $1]$ |
| $(3,7,2)$ | $(2,7,3)$ |  |  |
| 3 | $(2,2,1)$, |  | $[1$, |
| $(1,1,3)$, | $(3,1,1)$, | $(2,3,3)$ | 1, |
| $(2,7,3)$, | $(1,2,2)$, |  | $-]$ |
| $(3,0,3)$ | $(3,7,2)$ |  |  |
|  |  |  |  |

## Round 4

|  | Receive | Send | Next-hops |
| :---: | :---: | :---: | :---: |
| 1 |  |  | $[-$, |
| $(1,0,1)$ | $(3,3,2)$, |  | 2, |
| $(2,2,1)$, | $(2,3,3)$ |  | $3]$ |
| $(3,1,1)$ |  |  |  |
| 2 |  | $[1$, |  |
| $(1,2,2)$, | $(2,3,3)$ |  | ,- |
| $(2,0,2)$, |  |  |  |
| $(3,3,2)$ |  | $[1$, |  |
| 3 |  |  | 1, |
| $(1,1,3)$, | $(3,3,2)$ |  | $-]$ |
| $(2,3,3)$, |  |  |  |

## Why not Spanning Tree Protocol? Why Distance "Vector"?

- The same algorithm applies to all destinations
- Each node announces distance to each dest
- I am distance d_A away from node A
- I am distance d_B away from node B
- I am distance d_C away from node C
- ...
- Nodes are exchanging a vector of distances

## Distance Vector Protocol

- Messages (Y,d,X): For root Y; From node X; advertising a distance d to Y
- Initially each switch X initializes its routing table to ( $\mathrm{X}, 0,-$ ) and distance infinity to all other destinations
- Switches announce their entire distance vectors (routing table w/0 next hops)
- Upon receiving a routing table from a node (say $X$ ), each node does:
- For each destination $Y$ in the announcement (distance $(X, Y)=d$ ):
- If current_distance_to_Y > d + cost of link to $X$ :
- update current_distance_to_Y = d
- update next_hop_to_destination $=X$
- If shortest distance to any destination changed, send all neighbors your distance vectors

## Two Aspects to This Approach

- Protocol:
- Exchanging that routing information with neighbors
- What and when for exchanges
- RIP is a protocol that implements DV (IETF RFC 2080)
- Algorithm:
- How to use the information from your neighbors to update your own routing tables?

## Group Exercise:

## Lets run the Protocol again on this example

 (this time with distance vectors)

## Round 1

|  | distance | next-hop |
| :---: | :---: | :---: | :---: |
| 1 | 0 | - |
| 2 | infinity |  |
| 3 | infinity |  |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | infinity |  |
| 2 | 0 | - |
| 3 | infinity |  |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | infinity |  |
| 2 | infinity |  |
| 3 | 0 | - |

## Round 2

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 0 | - |
| 2 | 2 | 2 |
| 3 | 1 | 3 |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 2 | 1 |
| 2 | 0 | - |
| 3 | 7 | 3 |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 1 | 1 |
| 2 | 7 | 2 |
| 3 | 0 | - |

## Round 3

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 2 | 1 |
| 2 | 0 | - |
| 3 | 3 | 1 |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 1 | 1 |
| 2 | 3 | 1 |
| 3 | 0 | - |

## Round 4

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 2 | 1 |
| 2 | 0 | - |
| 3 | 3 | 1 |

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 1 | 1 |
| 2 | 3 | 1 |
| 3 | 0 | - |

## From Algorithm to Protocol

- Algorithm:
- Nodes use Bellman-Ford to compute distances
- Protocol
- Nodes exchange distance vectors
- Update their own routing tables
- And exchange again...
- Details: when to exchange, what to exchange, etc....

## A More Complicated Case

- The three node network:
- Everyone was neighbors with everyone else
-What happens in a larger network?
- Lets see ....

## Group Exercise:

## Lets run the Protocol on this example

## (this time with next-hops)

## Round 1

|  | distance | NH |
| :---: | :---: | :---: |
| x | infinity |  |
| y | 0 | - |
| $z$ | infinity |  |
| v | infinity |  |

|  | distance | NH |
| :---: | :---: | :---: |
| $\mathbf{x}$ | infinity |  |
| $y$ | infinity |  |
| $z$ | 0 | - |
| v | infinity |  |

|  | distance | NH |
| :---: | :---: | :---: |
| $x$ | 0 | - |
| $y$ | infinity |  |
| $z$ | infinity |  |
| $\mathbf{v}$ | infinity |  |

|  | distance | NH |
| :---: | :---: | :---: |
| x | infinity |  |
| y | infinity |  |
| z | infinity |  |
| v | 0 | - |

## Round 2

|  | distance | NH |
| :---: | :---: | :---: |
| $\mathbf{x}$ | 1 | x |
| y | 0 | - |
| $z$ | 3 | $z$ |
| l | infinity |  |

|  | distance | NH |
| :---: | :---: | :---: |
| x | infinity |  |
| y | 3 | y |
| z | 0 | - |
| v | 1 | v |
| $\mathbf{z}$ |  |  |
|  |  |  |
| $\mathbf{1}$ |  |  |
|  |  |  |
| $\mathbf{V}$ |  |  |

|  | distance | NH |
| :---: | :---: | :---: |
| x | 0 | - |
| y | 1 | y |
| z | infinity |  |
| v | 2 | v |

|  | distance | NH |
| :---: | :---: | :---: |
| x | 2 | x |
| y | infinity |  |
| z | 1 | z |
| v | 0 | - |

## Round 3

|  | distance | NH |
| :---: | :---: | :---: |
| x | 1 | x |
| y | 0 | - |
| z | 3 | z |
| v | 3 | x |

|  | distance | NH |
| :---: | :---: | :---: |
| $\mathbf{x}$ | 3 | v |
| y | 3 | y |
| z | 0 | - |
| $\mathbf{v}$ | 1 | v |
| $\mathbf{z}$ |  |  |
|  |  |  |
| $\mathbf{1}$ |  |  |
|  |  |  |
| $\mathbf{V}$ |  |  |

|  | distance | NH |
| :---: | :---: | :---: |
| x | 0 | - |
| y | 1 | y |
| z | 3 | v |
| v | 2 | v |

|  | distance | NH |
| :---: | :---: | :---: |
| x | 2 | x |
| y | 3 | x |
| z | 1 | z |
| v | 0 | - |

## Other Aspects of Protocol

-When do you send messages?

- When any of your distances $d(u, v)$ change
- What about when $c(u, v)$ changes?
- Periodically, to ensure consistency between neighbors
- What information do you send?
- Could send entire vector
- Or just updated entries
- Do you send everyone the same information
- Consider the following slides

## Three node network

## Three node network

## Round 1

## Round 2

## Round 3

## Round 4

COUNT-TO-INFINITY problem!!!!

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 1 | 1 |
| 2 | 7 | 1 |
| 3 | 0 | - |

## Count-to-infinity problem

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 0 | - |
| 2 | 6 | 3 |
| 3 | 1 | 3 |

Not just due to failures:
Can happen with changes in cost!

|  | distance | next-hop |
| :---: | :---: | :---: |
| 1 | 1 | 1 |
| 2 | 7 | 1 |
| 3 | 0 | - |

## How Can You Fix This?

- Do not advertise a path back to the node that is the next hop on the path
- Called "split horizon"
- Telling them about your entry going through them
- Doesn't tell them anything new
- Perhaps misleads them that you have an independent path
- Another solution: if you are using a next-hop's path, then:
- Tell them not to use your path (by telling them cost of infinity)
- Called "poisoned reverse"

## Convergence

- Distance vector protocols can converge slowly
- While these corner cases are rare
- The resulting convergence delays can be significant

## Comparison of Scalability

- Link-State:
- Global flood: each router's link-state (\#ports)
- Send it once per link event, or periodically
- Distance Vector:
- Send longer vector (\#dest) just to neighbors
- But might end up triggering their updates
- Send it every time DV changes (which can be often)
- Tradeoff:
- LS: Send it everywhere and be done in predictable time
- DV: Send locally, and perhaps iterate until convergence

## End of Distance-vector Routing

Now you know just as much as my PhD students :-)
