Texture Mapping

 So we make the shading parameters vary across the surface

[Foley et al. / Perlin]

Texture mapping

Adds visual complexity; makes appealing images

Texture mapping

- Color is not the same everywhere on a surface
 - one solution: multiple primitives
- Want a function that assigns a color to each point
 - the surface is a 2D domain, so that is essentially an image
 - can represent using any image representation
 - raster texture images are very popular

A definition

Texture mapping: a technique of defining surface properties (especially shading parameters) in such a way that they vary as a function of position on the surface.

- · This is very simple!
 - but it produces complex-looking effects

Cornell CS465 Fall 2006 • Lecture 14

Examples

- Wood gym floor with smooth finish
 - diffuse color k_D varies with position
 - specular properties k_s, n are constant
- · Glazed pot with finger prints
 - diffuse and specular colors k_D , k_S are constant
 - specular exponent n varies with position
- Adding dirt to painted surfaces
- · Simulating stone, fabric, ...
 - in many cases textures are used to approximate effects of small-scale geometry
 - · they look flat but are a lot better than nothing

Mapping textures to surfaces

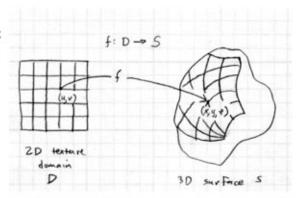

- Usually the texture is an image (function of u, v)
 - the big question of texture mapping: where on the surface does the image go?
 - obvious only for a flat rectangle the same shape as the image
 - otherwise more interesting
- Note that 3D textures also exist.
 - texture is a function of (u, v, w)
 - can just evaluate texture at 3D surface point
 - good for solid materials
 - often defined procedurally

Mapping textures to surfaces

- · "Putting the image on the surface"
 - this means we need a function f that tells where each point on the image goes
 - this looks a lot like a parametric surface function
 - for parametric surfaces you get f for free

Texture coordinate functions

- Non-parametrically defined surfaces: more to do
 - can't assign texture coordinates as we generate the surface
 - need to have the inverse of the function f
- Texture coordinate fn.

$$\phi: S \to \mathbb{R}^2$$

for a vtx. at **p** get texture at f (**p**)

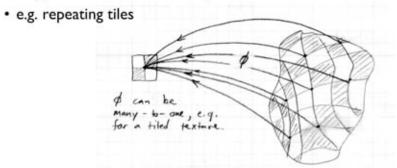

Cornell CS465 Fall 2006 • Lecture 14

Texture coordinate functions

- Mapping from S to D can be many-to-one
 - that is, every surface point gets only one color assigned
 - but it is OK (and in fact useful) for multiple surface points to be mapped to the same texture point

Texture coordinate functions

· Define texture image as a function

$$T:D\to C$$

- where C is the set of colors for the diffuse component
- · Diffuse color (for example) at point **p** is then

$$k_D(\mathbf{p}) = T(\phi(\mathbf{p}))$$

Examples of coordinate functions

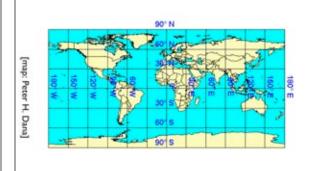

- A rectangle
 - image can be mapped directly, unchanged

Cornell CS465 Fall 2006 • Lecture 14

© 2006 Steve Marschner • 13

Examples of coordinate functions

- · For a sphere: latitude-longitude coordinates
 - f maps point to its latitude and longitude

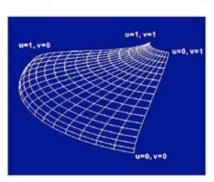

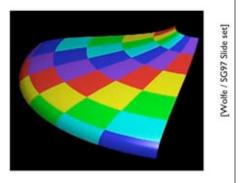

Cornell CS465 Fall 2006 • Lecture 14

@ 2006 Steve Marschner • 14

Examples of coordinate functions

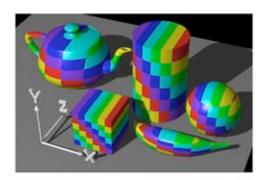

- A parametric surface (e.g. spline patch)
 - surface parameterization gives mapping function directly (well, the inverse of the parameterization)

Examples of coordinate functions

- · For non-parametric surfaces it is trickier
 - directly use world coordinates
 - · need to project one out

Examples of coordinate functions

- Triangles
 - specify (u,v) for each vertex
 - define (u,v) for interior by linear interpolation

Barycentric coordinates (will see again)

- · A coordinate system for triangles (will see this again)
 - interior point as convex affine combination of vertices

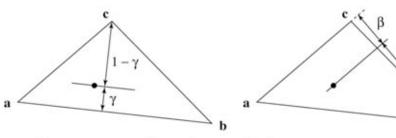

$$\begin{aligned} \mathbf{p} &= \mathbf{a} + \beta (\mathbf{b} - \mathbf{a}) + \gamma (\mathbf{c} - \mathbf{a}) \\ \alpha &= 1 - \beta - \gamma \\ \mathbf{p} &= \alpha \mathbf{a} + \beta \mathbf{b} + \gamma \mathbf{c} \\ \alpha + \beta + \gamma &= 1 \end{aligned}$$

- Geometric viewpoint: areas

Barycentric coordinates

- A coordinate system for triangles
 - geometric viewpoint: distance ratios perpendicular to edges

- · Texture coordinate interpolation
 - $-u = \alpha u_a + \beta u_b + \gamma u_c; v = \alpha v_a + \beta v_b + \gamma v_c$

Texture coordinates on meshes

- Texture coordinates become per-vertex data like vertex positions
 - can think of them as a second position: each vertex has a position in 3D space and in 2D texure space
- How to come up with vertex (u,v)s?
 - use any or all of the methods just discussed
 - in practice this is how you implement those for curved surfaces approximated with triangles
 - use some kind of optimization
 - try to choose vertex (u,v)s to result in a smooth, low distortion map
