Announcements

- In-class exam on Friday
- Cumulative
- Open-book / open-note

Segmentation by min cut

- The partitions S and T formed by the min cut give the optimal foreground and background segmentation
- I.e., the resulting labels minimize

$$E(d) = E_d(d) + \lambda E_s(d)$$

Topics – image processing

- Filtering
- Edge detection
- Image resampling / aliasing / interpolation
- Feature detection
 - Harris corners
 - SIFT
 - Invariant features
- Feature matching

Topics – 2D geometry

- Image transformations
- Image alignment / least squares
- RANSAC
- Panoramas
- Optical flow

Topics – 3D geometry

- Cameras
- Perspective projection
- Single-view modeling
- Stereo
- Two-view geometry (F-matrices, E-matrices)
- Structure from motion
- Multi-view stereo

Topics – recognition

- Skin detection / probabilistic modeling
- Eigenfaces
- Bag-of-words models
- Segmentation / graph cuts

Topics – Light, reflectance, cameras

- Light, BRDFS
- Photometric stereo
- Computational photography

Image Processing

Linear filtering

- One simple version: linear filtering (cross-correlation, convolution)
 - Replace each pixel by a linear combination of its neighbors
- The prescription for the linear combination is called the “kernel” (or “mask”, “filter”)

Convolution

- Same as cross-correlation, except that the kernel is “flipped” (horizontally and vertically)

$$G[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k H[u, v] F[i - u, j - v]$$

This is called a **convolution** operation:

$$G = H * F$$

- Convolution is **commutative** and **associative**

Gaussian Kernel

$$G_{\sigma} = \frac{1}{2\pi\sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}}$$

Image gradient

- The *gradient* of an image: $\nabla f = \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right]$

The gradient points in the direction of most rapid increase in intensity

The *edge strength* is given by the gradient magnitude:

$$\|\nabla f\| = \sqrt{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}$$

The gradient direction is given by:

$$\theta = \tan^{-1} \left(\frac{\partial f}{\partial y} / \frac{\partial f}{\partial x} \right)$$

- how does this relate to the direction of the edge?

Finding edges

gradient magnitude

Finding edges

thinning

(non-maximum suppression)

Image sub-sampling

1/2

1/4 (2x zoom)

1/8 (4x zoom)

Why does this look so cruffy?

Subsampling with Gaussian pre-filtering

Gaussian 1/2

G 1/4

G 1/8

- Solution: filter the image, *then* subsample

Image interpolation

*

“Ideal” reconstruction

Nearest-neighbor interpolation

Linear interpolation

Gaussian reconstruction

Image interpolation

Original image:  x 10

Nearest-neighbor interpolation

Bilinear interpolation

Bicubic interpolation

The second moment matrix

The surface $E(u,v)$ is locally approximated by a quadratic form.

$$E(u, v) \approx Au^2 + 2Buv + Cv^2$$
$$\approx \begin{bmatrix} u & v \end{bmatrix} \underbrace{\begin{bmatrix} A & B \\ B & C \end{bmatrix}}_H \begin{bmatrix} u \\ v \end{bmatrix}$$

$$A = \sum_{(x,y) \in W} I_x^2$$

$$B = \sum_{(x,y) \in W} I_x I_y$$

$$C = \sum_{(x,y) \in W} I_y^2$$

The Harris operator

λ_{\min} is a variant of the “Harris operator” for feature detection

$$f = \frac{\lambda_1 \lambda_2}{\lambda_1 + \lambda_2}$$
$$= \frac{\mathit{determinant}(H)}{\mathit{trace}(H)}$$

- The *trace* is the sum of the diagonals, i.e., $\mathit{trace}(H) = h_{11} + h_{22}$
- Very similar to λ_{\min} but less expensive (no square root)
- Called the “Harris Corner Detector” or “Harris Operator”
- Lots of other detectors, this is one of the most popular

Laplacian of Gaussian

- “Blob” detector

$$* \text{LoG} =$$

- Find maxima *and minima* of LoG operator in space and scale

Scale-space blob detector: Example

sigma = 11.9912

Feature distance

How to define the difference between two features f_1, f_2 ?

- Better approach: ratio distance = $\|f_1 - f_2\| / \|f_1 - f_2'\|$
 - f_2 is best SSD match to f_1 in I_2
 - f_2' is 2nd best SSD match to f_1 in I_2
 - gives large values for ambiguous matches

I_1

I_2

2D Geometry

Parametric (global) warping

$\mathbf{p} = (x, y)$

$\mathbf{p}' = (x', y')$

- Transformation T is a coordinate-changing machine:

$$\mathbf{p}' = T(\mathbf{p})$$

- What does it mean that T is global?

- Is the same for any point \mathbf{p}
- can be described by just a few numbers (parameters)

- Let's consider *linear* xforms (can be represented by a 2D matrix):

$$\mathbf{p}' = \mathbf{T}\mathbf{p} \quad \begin{bmatrix} x' \\ y' \end{bmatrix} = \mathbf{T} \begin{bmatrix} x \\ y \end{bmatrix}$$

2D image transformations

Name	Matrix	# D.O.F.	Preserves:	Icon
translation	$\begin{bmatrix} \mathbf{I} & \mathbf{t} \end{bmatrix}_{2 \times 3}$	2	orientation + ...	
rigid (Euclidean)	$\begin{bmatrix} \mathbf{R} & \mathbf{t} \end{bmatrix}_{2 \times 3}$	3	lengths + ...	
similarity	$\begin{bmatrix} s\mathbf{R} & \mathbf{t} \end{bmatrix}_{2 \times 3}$	4	angles + ...	
affine	$\begin{bmatrix} \mathbf{A} \end{bmatrix}_{2 \times 3}$	6	parallelism + ...	
projective	$\begin{bmatrix} \tilde{\mathbf{H}} \end{bmatrix}_{3 \times 3}$	8	straight lines	

These transformations are a nested set of groups

- Closed under composition and inverse is a member

Projective Transformations aka Homographies aka Planar Perspective Maps

$$\mathbf{H} = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & 1 \end{bmatrix}$$

Called a *homography*
(or *planar perspective map*)

Inverse Warping

- Get each pixel $g(x',y')$ from its corresponding location $(x,y) = T^{-1}(x',y')$ in $f(x,y)$
- Requires taking the inverse of the transform

Affine transformations

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} a & b & c \\ d & e & f \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} ax + by + c \\ dx + ey + f \\ 1 \end{bmatrix}$$

Affine transformations

- Matrix form

$$\begin{bmatrix} x_1 & y_1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_1 & y_1 & 1 \\ x_2 & y_2 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_2 & y_2 & 1 \\ \vdots & & & & & \\ x_n & y_n & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_n & y_n & 1 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ d \\ e \\ f \end{bmatrix} = \begin{bmatrix} x'_1 \\ y'_1 \\ x'_2 \\ y'_2 \\ \vdots \\ x'_n \\ y'_n \end{bmatrix}$$

A **t** = **b**

$2n \times 6$ 6×1 $2n \times 1$

RANSAC

- General version:
 1. Randomly choose s samples
 - Typically s = minimum sample size that lets you fit a model
 2. Fit a model (e.g., line) to those samples
 3. Count the number of inliers that approximately fit the model
 4. Repeat N times
 5. Choose the model that has the largest set of inliers

Projecting images onto a common plane

each image is warped
with a homography \mathbf{H}

Can't create a 360 panorama this way...

mosaic PP

Optical flow

Lucas-Kanade flow

- How to get more equations for a pixel?
 - Basic idea: impose additional constraints
 - Lucas-Kanade: pretend the pixel's neighbors have the same (u,v)
 - If we use a 5x5 window, that gives us 25 equations per pixel!

$$0 = I_t(\mathbf{p}_i) + \nabla I(\mathbf{p}_i) \cdot [u \ v]$$

$$\begin{bmatrix} I_x(\mathbf{p}_1) & I_y(\mathbf{p}_1) \\ I_x(\mathbf{p}_2) & I_y(\mathbf{p}_2) \\ \vdots & \vdots \\ I_x(\mathbf{p}_{25}) & I_y(\mathbf{p}_{25}) \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = - \begin{bmatrix} I_t(\mathbf{p}_1) \\ I_t(\mathbf{p}_2) \\ \vdots \\ I_t(\mathbf{p}_{25}) \end{bmatrix}$$

A d b
 25×2 2×1 25×1

3D Geometry

Pinhole camera

- Add a barrier to block off most of the rays
 - This reduces blurring
 - The opening known as the **aperture**
 - How does this transform the image?

Perspective Projection

Projection is a matrix multiply using homogeneous coordinates:

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1/d & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ -z/d \end{bmatrix} \Rightarrow \left(-d\frac{x}{z}, -d\frac{y}{z}\right)$$

divide by third coordinate

This is known as **perspective projection**

- The matrix is the **projection matrix**

Projection matrix

$$\mathbf{\Pi} = \mathbf{K} \underbrace{\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}}_{\text{projection}} \underbrace{\begin{bmatrix} \mathbf{R} & \begin{matrix} 0 \\ 0 \\ 0 \end{matrix} \\ 0 & 0 & 0 & 1 \end{bmatrix}}_{\text{rotation}} \underbrace{\begin{bmatrix} \mathbf{I}_{3 \times 3} & -\mathbf{c} \\ 0 & 0 & 0 & 1 \end{bmatrix}}_{\text{translation}}$$

$$\left[\mathbf{R} \mid \underbrace{-\mathbf{R}\mathbf{c}} \right]$$

(\mathbf{t} in book's notation)

$$\mathbf{\Pi} = \mathbf{K} \left[\mathbf{R} \mid -\mathbf{R}\mathbf{c} \right]$$

Point and line duality

- A line l is a homogeneous 3-vector
- It is \perp to every point (ray) p on the line: $l \cdot p = 0$

What is the line l spanned by rays p_1 and p_2 ?

- l is \perp to p_1 and $p_2 \Rightarrow l = p_1 \times p_2$
- l can be interpreted as a *plane normal*

What is the intersection of two lines l_1 and l_2 ?

- p is \perp to l_1 and $l_2 \Rightarrow p = l_1 \times l_2$

Points and lines are *dual* in projective space

Vanishing points

- Properties
 - Any two parallel lines (in 3D) have the same vanishing point v
 - The ray from C through v is parallel to the lines
 - An image may have more than one vanishing point
 - in fact, every image point is a potential vanishing point

Measuring height

Your basic stereo algorithm

For each epipolar line

For each pixel in the left image

- compare with every pixel on same epipolar line in right image
- pick pixel with minimum match cost

Improvement: match *windows*

Stereo as energy minimization

- Better objective function

$$E(d) = \underbrace{E_d(d)}_{\text{match cost}} + \lambda \underbrace{E_s(d)}_{\text{smoothness cost}}$$

Want each pixel to find a good match in the other image

Adjacent pixels should (usually) move about the same amount

Fundamental matrix

- This *epipolar geometry* of two views is described by a Very Special 3x3 matrix \mathbf{F} , called the *fundamental matrix*
- \mathbf{F} maps (homogeneous) *points* in image 1 to *lines* in image 2!
- The epipolar line (in image 2) of point \mathbf{p} is: $\mathbf{F}\mathbf{p}$
- *Epipolar constraint* on corresponding points: $\mathbf{q}^T \mathbf{F}\mathbf{p} = 0$

Epipolar geometry demo

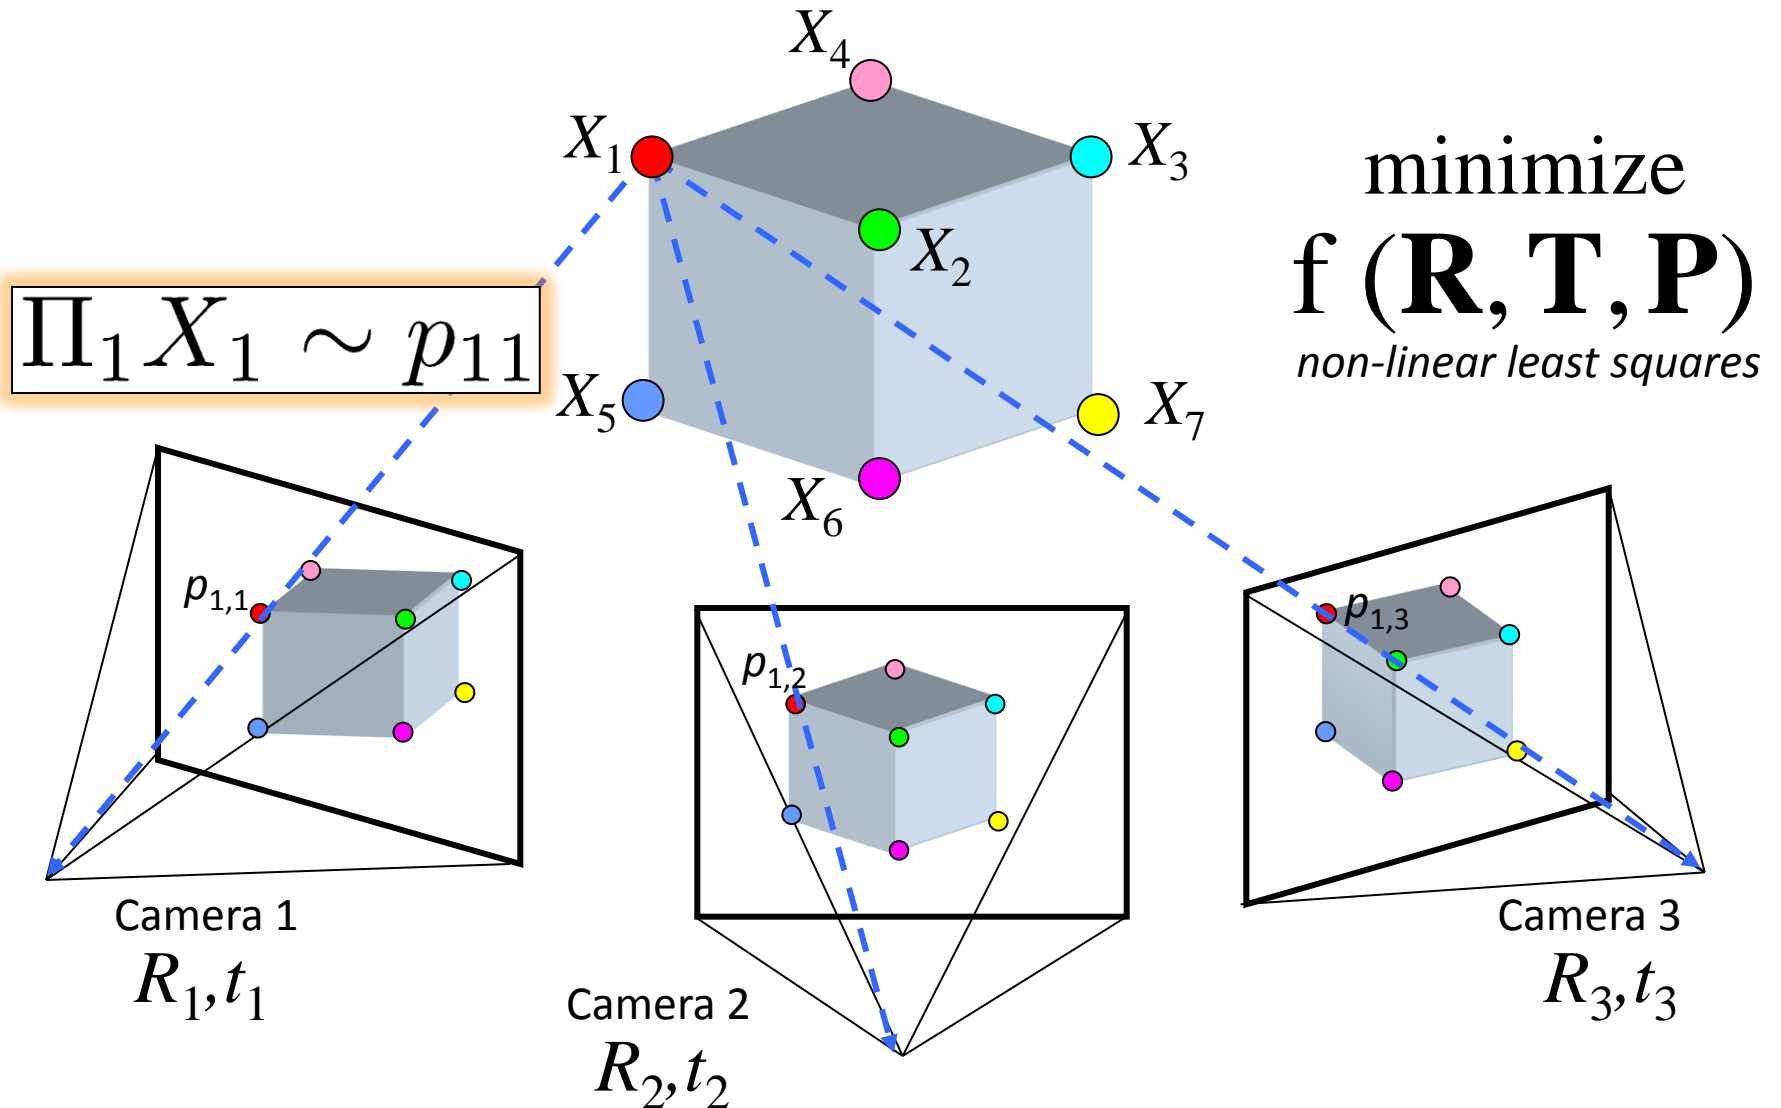

8-point algorithm

$$\begin{bmatrix}
 u_1 u_1' & v_1 u_1' & u_1' & u_1 v_1' & v_1 v_1' & v_1' & u_1 & v_1 & 1 \\
 u_2 u_2' & v_2 u_2' & u_2' & u_2 v_2' & v_2 v_2' & v_2' & u_2 & v_2 & 1 \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
 u_n u_n' & v_n u_n' & u_n' & u_n v_n' & v_n v_n' & v_n' & u_n & v_n & 1
 \end{bmatrix}
 \begin{bmatrix}
 f_{11} \\
 f_{12} \\
 f_{13} \\
 f_{21} \\
 f_{22} \\
 f_{23} \\
 f_{31} \\
 f_{32} \\
 f_{33}
 \end{bmatrix}
 = 0$$

- In reality, instead of solving $\mathbf{A}\mathbf{f} = 0$, we seek \mathbf{f} to minimize $\|\mathbf{A}\mathbf{f}\|$, least eigenvector of $\mathbf{A}^T \mathbf{A}$.

Structure from motion

Stereo: another view

Fig. 5. SSD values versus inverse distance: (a) $B = b$; (b) $B = 2b$; (c) $B = 3b$; (d) $B = 4b$; (e) $B = 5b$; (f) $B = 6b$; (g) $B = 7b$; (h) $B = 8b$. The horizontal axis is normalized such that $8bF = 1$.

Fig. 6. Combining two stereo pairs with different baselines.

Fig. 7. Combining multiple baseline stereo pairs.

Recognition

Face detection

- Do these images contain faces? Where?

Skin classification techniques

Skin classifier

- Given $X = (R, G, B)$: how to determine if it is skin or not?
- Nearest neighbor
 - find labeled pixel closest to X
 - choose the label for that pixel
- Data modeling
 - fit a model (curve, surface, or volume) to each class
- Probabilistic data modeling
 - fit a probability model to each class

Dimensionality reduction

The set of faces is a “subspace” of the set of images

- Suppose it is K dimensional
- We can find the best subspace using PCA
- This is like fitting a “hyper-plane” to the set of faces
 - spanned by vectors $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_K$
 - any face $\mathbf{x} \approx \bar{\mathbf{x}} + a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + \dots + a_k\mathbf{v}_k$

Eigenfaces

PCA extracts the eigenvectors of \mathbf{A}

- Gives a set of vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \dots$
- Each one of these vectors is a direction in face space
 - what do these look like?

Bag-of-words models

Related problem: binary segmentation

- Suppose we want to segment an image into foreground and background

Binary segmentation as energy minimization

- Define a labeling L as an assignment of each pixel with a 0-1 label (background or foreground)
- Problem statement: find the labeling L that minimizes

$$E(L) = \underbrace{E_d(L)}_{\text{match cost}} + \lambda \underbrace{E_s(L)}_{\text{smoothness cost}}$$

(“how similar is each labeled pixel to the foreground / background?”)

Light, reflectance, cameras

Radiometry

What determines the brightness of an image pixel?

Classic reflection behavior

Photometric stereo

$$I_1 = k_d \mathbf{N} \cdot \mathbf{L}_1$$

$$I_2 = k_d \mathbf{N} \cdot \mathbf{L}_2$$

$$I_3 = k_d \mathbf{N} \cdot \mathbf{L}_3$$

Can write this as a matrix equation:

$$\begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = k_d \begin{bmatrix} \mathbf{L}_1^T \\ \mathbf{L}_2^T \\ \mathbf{L}_3^T \end{bmatrix} \mathbf{N}$$

Example

Computational photography

The “analog” camera has changed very little in >100 yrs

- we’re unlikely to get there following this path

More promising is to combine “analog” optics with computational techniques

- “Computational cameras” or “Computational photography”

This lecture will survey techniques for producing higher quality images by combining optics and computation

Common themes:

- take multiple photos
- modify the camera

Questions?

Good luck!
