Lecture 38: Training Neural Networks

CS 4670/5670 Sean Bell

(Note: I'm not sure whether or not Tay.ai used neural nets)

(Recap) How do you actually train these things?

Roughly speaking:

Gather labeled data

Find a ConvNet architecture

Minimize the loss

(Recap) Training a convolutional neural network

- Split and preprocess your data
- Choose your network architecture
- Initialize the weights
- Find a learning rate and regularization strength
- Minimize the loss and monitor progress
- Fiddle with knobs

(Recap) (1) Data preprocessing

Subtract the mean

An input image (256x256)

Minus sign

The mean input image

And randomly take a 224x224 sub-crop (dynamically)

Figure: Alex Krizhevsky

(2) Choose your architecture

Toy example: one hidden layer of size 50

(3) Initialize your weights

Set the weights to small random numbers:

W = np.random.randn(D, H) * 0.001

(matrix of small random numbers drawn from a Gaussian distribution)

(the magnitude is important and this is not optimal — more on this later)

Set the bias to zero (or small nonzero):

(3) Check that the loss is reasonable

```
def init_two_layer_model(input_size, hidden_size, output_size):
    # initialize a model
    model = {}
    model['W1'] = 0.0001 * np.random.randn(input_size, hidden_size)
    model['b1'] = np.zeros(hidden_size)
    model['W2'] = 0.0001 * np.random.randn(hidden_size, output_size)
    model['b2'] = np.zeros(output_size)
    return model
```

```
model = init_two_layer_model(32*32*3, 50, 10) # input size, hidden size, number of classes
loss, grad = two_layer_net(X_train, model, y_train, 0.0)
print loss
disable regularization
```

returns the loss and the gradient for all parameters

(3) Check that the loss is reasonable

```
def init_two_layer_model(input_size, hidden_size, output_size):
    # initialize a model
    model = {}
    model['W1'] = 0.0001 * np.random.randn(input_size, hidden_size)
    model['b1'] = np.zeros(hidden_size)
    model['W2'] = 0.0001 * np.random.randn(hidden_size, output_size)
    model['b2'] = np.zeros(output_size)
    return model
```

model = init_two_layer_model(32*32*3, 50, 10) # input_size, hidden size, number of classes
loss, grad = two_layer_net(X_train, model, y_train, 1e3) Crank up regularization
print loss

loss went up, good. (sanity check)

(4) Overfit a small portion of the data

Details:

'sgd': vanilla gradient descent (no momentum etc)

learning_rate_decay = 1: constant learning rate

sample_batches = False (full gradient descent, no batches)

epochs = 200: number of passes through the data

(4) Overfit a small portion of the data

100% accuracy on the training set (good)

Finished epoch 1 / 200: cost 2.302603, train: 0.400000, val 0.400000, lr 1.000000e-03

finished optimization. best validation accuracy: 1.000000	

Let's start with small regularization and find the learning rate that makes the loss decrease:

<pre>model = init_two_layer_model(32*32*3, 50, 10) # input size, hidden size, number of classe trainer = ClassifierTrainer() best_model, stats = trainer.train(X_train, y_train, X_val, y_val,</pre>
<pre>learning_rate=1e-6, verbose=True)</pre>
Finished epoch 1 / 10: cost 2.302576, train: 0.080000, val 0.103000, lr 1.000000e-06
Finished epoch 2 / 10: cost 2.302582, train: 0.121000, val 0.124000, lr 1.000000e-06
Finished epoch 3 / 10: cost 2.302558, train: 0.119000, val 0.138000, lr 1.000000e-06
Finished epoch 4 / 10: cost 2.302519, train: 0.127000, val 0.151000, lr 1.000000e-06
Finished epoch 5 / 10: cost 2.302517, train: 0.158000, val 0.171000, lr 1.000000e-06
Finished epoch 6 / 10: cost 2.302518, train: 0.179000, val 0.172000, lr 1.000000e-06
Finished epoch 7 / 10: cost 2.302466, train: 0.180000, val 0.176000, lr 1.000000e-06
Finished epoch 8 / 10: cost 2.302452, train: 0.175000, val 0.185000, lr 1.000000e-06
Finished epoch 9 / 10: cost 2.302459, train: 0.206000, val 0.192000, lr 1.000000e-06
Finished epoch 10 / 10 cost 2.302420 train: 0.190000, val 0.192000, lr 1.000000e-06
finished optimization. best validation accuracy: 0.192000

Loss barely changesWhy is the accuracy 20%?(learning rate is too low or regularization too high)

Learning rate: 1e6 — what could go wrong?

/home/karpathy/cs231n/code/cs231n/classifiers/neural_net.py:50: RuntimeWarning: divide by zero en
countered in log

Loss is NaN —> learning rate is too high

Learning rate: 1e6 — what could go wrong?

A weight somewhere in the network

Learning rate: 3e-3

Finished epoch 1 / 10: cost 2.186654, train: 0.308000, val 0.306000, lr 3.000000e-03 Finished epoch 2 / 10: cost 2.176230, train: 0.330000, val 0.350000, lr 3.000000e-03 Finished epoch 3 / 10: cost 1.942257, train: 0.376000, val 0.352000, lr 3.000000e-03 Finished epoch 4 / 10: cost 1.827868, train: 0.329000, val 0.310000, lr 3.000000e-03 Finished epoch 5 / 10: cost inf, train: 0.128000, val 0.128000, lr 3.000000e-03 Finished epoch 6 / 10: cost inf, train: 0.144000, val 0.147000, lr 3.000000e-03

Loss is inf -> still too high

But now we know we should be searching the range [1e-5 ... 1e-3]

Coarse to fine search

First stage: only a few epochs (passes through the data) to get a rough idea

Second stage: longer running time, finer search

Tip: if loss > 3 * original loss, quit early (learning rate too high)

Coarse to fine search

$max_count = 100$

Remember this is just a 2 layer neural net with 50 neurons

- 53%

Normally, you don't have the budget for lots of crossvalidation —> visualize as you go

Plot the loss

For very small learning rates, the loss decreases linearly and slowly

(Why linearly?)

Larger learning rates tend to look more exponential

Normally, you don't have the budget for lots of crossvalidation —> visualize as you go

time

lossfunctions

They are a window to your model's heart.

Contribute loss functions to @karpathy. It doesn't matter if your loss functions are flat, converge, diverge, step or oscillate (or any combination of the above). All loss functions are computed beautiful in their own way and are sought after with equal tenacity.

ARCHIVE

Ah, the Sharp Corner Loss (SCL). Bad initialization a prime suspect.

1 note

A beautiful rainbow of learning! This code is definitely bug free. Learning rate decay might be slightly too high.

Looks good but mysterious high frequency harmonics are mysterious

2 notes

 \odot

. 'i

. . .

When you stare at loss functions for a while you start seeing things

40 notes

Visualize the accuracy

Visualize the weights

Noisy weights: possibly regularization not strong enough

Visualize the weights

Nice clean weights: training is proceeding well

Figure: Alex Krizhevsky , Andrej Karpathy

Learning rate schedule

How do we change the learning rate over time? Various choices:

- Step down by a factor of 0.1 every 50,000 mini-batches (used by SuperVision [Krizhevsky 2012])
- Decrease by a factor of 0.97 every epoch (used by GoogLeNet [Szegedy 2014])
- Scale by sqrt(1-t/max_t) (used by BVLC to re-implement GoogLeNet)
- Scale by 1/t
- Scale by exp(-t)

Summary of things to fiddle

- Network architecture
- Learning rate, decay schedule, update type
- Regularization (L2, L1, maxnorm, dropout, ...)
- Loss function (softmax, SVM, ...)
- Weight initialization

Neural network parameters

Questions?

Tricks for making training work better

Momentum

Simple but powerful improvement: Give some "momentum" to the parameters

Unfortunate nomenclature: the damping factor is called "momentum"

"Lesson from the trenches": well-tuned SGD with Momentum is very hard to beat for ConvNets

Momentum

Intuition behind momentum:

- Imagine a ball on the loss surface (its position is the current weight settings)

 Directions with lots of oscillations are damped

 Builds up speed in directions with a consistent gradient

"RMSprop"

On Geoff Hinton's coursera lecture 6a, he mentioned various "tricks" including "rmsprop"

Idea: track the moving average of squared gradients

```
cache = decay_rate * cache + (1 - decay_rate) * dx**2
x += - learning_rate * dx / np.sqrt(cache + 1e-8)
```

decay_rate is a hyper-parameter (typically 0.9, 0.99, or 0.999)
