IBM and Microsoft and BEA (collectively, the "Authors") hereby grant you permission to copy and display the WS-AtomicTransaction Specification (the "Specification"), in any medium without fee or royalty, provided that you include the following on ALL copies of the Specification, or portions thereof, that you make:

1. A link or URL to the Specification at this location.
2. The copyright notice as shown in the Specification.

The Authors and/or any other third party may have patents, patent applications, trademarks, copyrights, or other intellectual property rights covering subject matter in the Specification. EXCEPT FOR THE COPYRIGHT LICENSE GRANTED ABOVE, THE AUTHORS DO NOT GRANT, EITHER EXPRESSLY OR IMPLIEDLY, A LICENSE TO ANY INTELLECTUAL PROPERTY, INCLUDING PATENTS, THEY, OR ANY OTHER THIRD PARTIES, OWN OR CONTROL. Title to copyright in the Specification will at all times remain with the Authors. The example companies, organizations, products, domain names, e-mail addresses, logos, people, places, and events depicted herein are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, places, or events is intended or should be inferred.

THE SPECIFICATION IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE SPECIFICATION ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.
Abstract
This specification provides the definition of the atomic transaction coordination type that is to be used with the extensible coordination framework described in the WS-Coordination specification. The specification defines three specific agreement coordination protocols for the atomic transaction coordination type: completion, volatile two-phase commit, and durable two-phase commit. Developers can use any or all of these protocols when building applications that require consistent agreement on the outcome of short-lived distributed activities that have the all-or-nothing property.

Composable Architecture
By using the SOAP [SOAP] and WSDL [WSDL] extensibility model, SOAP-based and WSDL-based specifications are designed to work together to define a rich Web services environment. As such, WS-AtomicTransaction by itself does not define all features required for a complete solution. WS-AtomicTransaction is a building block used with other specifications of Web services (e.g., WS-Coordination, WS-Security) and application-specific protocols that are able to accommodate a wide variety of coordination protocols related to the coordination actions of distributed applications.

Status
WS-AtomicTransaction replaces Part I of the WS-Transaction specification released August 2002. A specification titled WS-BusinessActivity that replaces Part II of WS-Transaction will be released separately. WS-AtomicTransaction and related specifications are provided for use as-is and for review and evaluation only. Microsoft, BEA, and IBM will solicit your contributions and suggestions in the near future. Microsoft, BEA, and IBM make no warrantees or representations regarding the specification in any manner whatsoever.

Acknowledgments
The following individuals have provided invaluable input into the design of the WS-AtomicTransaction specification:
  Francisco Curbera, IBM
  Sanjay Dalal, BEA Systems
  Gert Drapers, Microsoft
  Don Ferguson, IBM
  Frank Leymann, IBM
  David Orchard, BEA Systems
  Jagan Peri, Microsoft
  John Shewchuk, Microsoft
  Alex Somogyi, BEA Systems
  Sanjiva Weerawarana, IBM
We also wish to thank the technical writers and development reviewers who provided feedback to improve the readability of the specification.

1. Introduction

The current set of Web service specifications [WSDL] [SOAP] defines protocols for Web service interoperability. Web services increasingly tie together a number of participants forming large distributed applications. The resulting activities may have complex structure and relationships.

The WS-Coordination specification defines an extensible framework for defining coordination types. This specification provides the definition of an atomic transaction coordination type used to coordinate activities having an "all or nothing" property. Atomic transactions commonly require a high level of trust between participants and are short in duration. The Atomic Transaction specification defines protocols that enable existing transaction processing systems to wrap their proprietary protocols and interoperate across different hardware and software vendors.

To understand the protocol described in this specification, the following assumptions are made:

- The reader is familiar with existing standards for two-phase commit protocols and with commercially available implementations of such protocols. Therefore this section includes only those details that are essential to understanding the protocols described.
The reader is familiar with the WS-Coordination [WSCOOR] specification that defines the framework for the WS-AtomicTransaction coordination protocols.

The reader is familiar with WS-Addressing [WSADDR] and WS-Policy [WSPOLICY].

Atomic transactions have an all-or-nothing property. The actions taken prior to commit are only tentative (i.e., not persistent and not visible to other activities). When an application finishes, it requests the coordinator to determine the outcome for the transaction. The coordinator determines if there were any processing failures by asking the participants to vote. If the participants all vote that they were able to execute successfully, the coordinator commits all actions taken. If a participant votes that it needs to abort or a participant does not respond at all, the coordinator aborts all actions taken. Commit makes the tentative actions visible to other transactions. Abort makes the tentative actions appear as if the actions never happened. Atomic transactions have proven to be extremely valuable for many applications. They provide consistent failure and recovery semantics, so the applications no longer need to deal with the mechanics of determining a mutually agreed outcome decision or to figure out how to recover from a large number of possible inconsistent states.

Atomic Transaction defines protocols that govern the outcome of atomic transactions. It is expected that existing transaction processing systems wrap their proprietary mechanisms and interoperate across different vendor implementations.

### 1.1 Notational Conventions

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC2119 [KEYWORDS].

Namespace URIs of the general form "some-URI" represents some application-dependent or context-dependent URI as defined in RFC2396 [URI].

### 1.2 Namespace

The XML namespace [XML-ns] URI that MUST be used by implementations of this specification is:

```
```

This is also used as the CoordinationContext type for atomic transactions.

The following namespaces are used in this document:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td><a href="http://www.w3.org/2001/12/soap-envelope">http://www.w3.org/2001/12/soap-envelope</a></td>
</tr>
</tbody>
</table>

If an action URI is used then the action URI MUST consist of the wsat namespace URI concatenated with the "#" character and the operation name. For example:

```
http://schemas.xmlsoap.org/ws/2003/09/wsat#Commit
```
1.3 XSD and WSDL Files
The following links hold the XML schema and the WSDL declarations defined in this document.
Soap bindings for the WSDL documents defined in this specification MUST use "document" for the style attribute.

2. Atomic Transaction Context
Atomic Transaction builds on WS-Coordination, which defines an activation and a registration service. Example message flows and a complete description of creating and registering for coordinated activities is found in the WS-Coordination specification [WSCOOR].
The Atomic Transaction coordination context must flow on all application messages involved with the transaction.
Atomic Transaction adds the following semantics to the CreateCoordinationContext operation on the activation service.

• If the request includes the CurrentContext element, the target coordinator is interposed as a subordinate to the coordinator stipulated inside the CurrentContext element.
• If the request does not include a CurrentContext element, the target coordinator creates a new transaction and acts as the root.

A coordination context may have an Expires attribute. This attribute specifies the earliest point in time at which a transaction may be terminated solely due to its length of operation. From that point forward, the transaction manager may elect to unilaterally roll back the transaction, so long as it has not transmitted a Commit or a Prepared notification.

The Atomic Transaction protocol is identified by the following coordination type:

3 Atomic Transaction Protocols
This specification defines the following protocols for atomic transactions.

• **Completion**: The completion protocol initiates commitment processing. Based on each protocol's registered participants, the coordinator begins with Volatile 2PC then proceeds through Durable 2PC. The final result is signaled to the initiator.
• **Two-Phase Commit (2PC)**: The 2PC protocol coordinates registered participants to reach a commit or abort decision, and ensures that all participants are informed of the final result. The 2PC protocol has two variants:
  • **Volatile 2PC**: Participants managing volatile resources such as a cache should register for this protocol.
  • **Durable 2PC**: Participants managing durable resources such as a database should register for this protocol.

A participant can register for more than one of these protocols by sending multiple Register messages.
3.1 Preconditions
The correct operation of the protocols requires that a number of preconditions MUST be established prior to the processing:

1. The source MUST have knowledge of the destination's policies, if any, and the source MUST be capable of formulating messages that adhere to this policy.
2. If a secure exchange of messages is required, then the source and destination MUST have a security context.

3.2 Completion Protocol
The Completion protocol is used by an application to tell the coordinator to either try to commit or abort an atomic transaction. After the transaction has completed, a status is returned to the application.

An initiator registers for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2003/09/wsat#Completion

The diagram below illustrates the protocol abstractly:

The coordinator accepts:
Commit
Upon receipt of this notification, the coordinator knows that the participant has completed application processing and that it should attempt to commit the transaction.

Rollback
Upon receipt of this notification, the coordinator knows that the participant has terminated application processing and that it should abort the transaction.

The initiator accepts:
Committed
Upon receipt of this notification, the initiator knows that the coordinator reached a decision to commit.

Aborted
Upon receipt of this notification, the initiator knows that the coordinator reached a decision to abort.

Conforming implementations must implement Completion.
3.3 Two-Phase Commit Protocol

The Two-Phase Commit (2PC) protocol is a Coordination protocol that defines how multiple participants reach agreement on the outcome of an atomic transaction. The 2PC protocol has two variants: Durable 2PC and Volatile 2PC.

3.3.1 Volatile Two-Phase Commit Protocol

Upon receiving a Commit notification in the completion protocol, the root coordinator begins the prepare phase of all participants registered for the Volatile 2PC protocol. All participants registered for this protocol must respond before a Prepare is issued to a participant registered for Durable 2PC. Further participants may register with the coordinator until the coordinator issues a Prepare to any durable participant. A volatile recipient is not guaranteed to receive a notification of the transaction’s outcome.

Participants register for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2003/09/wsat#Volatile2PC

3.3.2 Durable Two-Phase Commit Protocol

After receiving a Commit notification in the completion protocol and upon successfully completing the prepare phase for Volatile 2PC participants, the root coordinator begins the Prepare phase for Durable 2PC participants. All participants registered for this protocol must respond Prepared or ReadOnly before a Commit notification is issued to a participant registered for either protocol.

Participants register for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2003/09/wsat#Durable2PC

3.3.3 2PC Diagram and Notifications

The diagram below illustrates the protocol abstractly:

![2PC Diagram](image_url)

The participant accepts:

Prepare

Upon receipt of this notification, the participant knows to enter phase 1 and vote on the outcome of the transaction. If the participant does not know of the
transaction, it must vote to abort. If the participant has already voted, it should resend the same vote.

Rollback
Upon receipt of this notification, the participant knows to abort, and forget, the transaction. This notification can be sent in either phase 1 or phase 2. Once sent, the coordinator may forget all knowledge of this transaction.

Commit
Upon receipt of this notification, the participant knows to commit the transaction. This notification can only be sent after phase 1 and if the participant voted to commit. If the participant does not know of the transaction, it must send a Committed notification to the coordinator.

The coordinator accepts:

Prepared
Upon receipt of this notification, the coordinator knows the participant is prepared and votes to commit the transaction.

ReadOnly
Upon receipt of this notification, the coordinator knows the participant votes to commit the transaction, and has forgotten the transaction. The participant does not wish to participate in phase 2.

Aborted
Upon receipt of this notification, the coordinator knows the participant has aborted, and forgotten, the transaction.

Committed
Upon receipt of this notification, the coordinator knows the participant has committed the transaction. That participant may be safely forgotten.

Replay
Upon receipt of this notification, the coordinator may assume the participant has suffered a recoverable failure. It should resend the last appropriate protocol notification.

Conforming implementations MUST implement the 2PC protocol.

4. Policy Assertions
WS-Policy [WSPOLICY], WS-PolicyAttachment [WSPOLICYATTACH], and WS-PolicyAssertions [WSPOLICYASSERT] collectively define a framework, model, and grammar for expressing the capabilities, requirements, and general characteristics of entities in an XML Web services-based system. This specification leverages the WS-Policy family of specifications to enable participants and coordinators to describe and advertise their capabilities and/or requirements. The set of policy assertions for atomic transaction is defined below.

4.1. Spec Version
The protocol determines invariants maintained by the reliable messaging endpoints and the directives used to track and manage the delivery of messages. The assertion that will be used to identify the protocol (and version) either used or supported (depending on context) is the wsp:SpecVersion assertion that is defined in the WS-PolicyAssertions specification [WSPOLICYASSERT].
An example use of this assertion to indicate an endpoint's support for the atomic transaction protocol follows:
<wsp:SpecVersion
wsp:Usage="wsp:Required"/>

4.2 Protocols
This section establishes well-known names for the protocols supported by atomic transactions.
The following pseudo schema defines these elements:
<wsat:Completion ... />
<wsat:DurableTwoPhaseCommit ... />
<wsat:VolatileTwoPhaseCommit ... />

The following describes the attributes and tags listed in the syntax above:
/wsat:Completion
   This element is a policy assertion as defined in WS-Policy Assertions. It indicates support for the Completion Protocol (Section 3.2)
/wsat:DurableTwoPhaseCommit
   This element is a policy assertion as defined in WS-Policy Assertions. It indicates support for the Two Phase Commit Protocol (Section 3.3.2)
/wsat:VolatileTwoPhaseCommit
   This element is a policy assertion as defined in WS-Policy Assertions. It indicates support for the Two Phase Commit Protocol (Section 3.3.1)

5. Transaction Faults
In addition to the faults defined in WS-Coordination, the following faults are available to Atomic Transaction implementations.

5.1 InconsistentInternalState
This fault is sent by a participant to indicate that it cannot fulfill its obligations. This indicates a global consistency failure and is an unrecoverable condition.
The qualified name of the fault code is:
wsat:InconsistentInternalState

6. Security Model
The security model for atomic transactions builds on the model defined in WS-Coordination [WSCOOR]. That is, services have policies specifying their requirements and requestors provide claims (either implicit or explicit) and the requisite proof of those claims. Coordination context creation establishes a base secret which can be delegated by the creator as appropriate.
Because atomic transactions represent a specific use case rather than the general nature of coordination contexts, additional aspects of the security model can be specified.

All access to atomic transaction protocol instances is on the basis of identity. The nature of transactions, specifically the uncertainty of systems means that the security context established to register for the protocol instance may not be available for the entire duration of the protocol.

Consider for example the scenarios where a participant has committed its part of the transaction, but for some reason the coordinator never receives acknowledgement of the commit. The result is that when communication is re-established in the future, the coordinator will attempt to confirm the commit status of the participant, but the participant, having committed the transaction and forgotten all information associated with it, no longer has access to the special keys associated with the token.

The participant can only prove its identity to the coordinator when it indicates that the specified transaction is not in its log and assumed committed. This is illustrated in the figure below:

![Diagram showing interaction between Coordinator and Participant](image)

There are, of course, techniques to mitigate this situation but such options will not always be successful. Consequently, when dealing with atomic transactions, it is critical that identity claims always be proven to ensure that correct access control is maintained by coordinators.

There is still value in coordination context-specific tokens because they offer a bootstrap mechanism so that all participants need not be pre-authorized. As well, it provides additional security because only those instances of an identity with access to the token will be able to securely interact with the coordinator (limiting privileges strategy). This is illustrated in the figure below:
The "list" of authorized participants ensures that application messages having a coordination context are properly authorized since altering the coordination context ID will not provide additional access unless (1) the bootstrap key is provided, or (2) the requestor is on the authorized participant "list" of identities.

7. Security Considerations

It is strongly RECOMMENDED that the communication between services be secured using the mechanisms described in WS-Security [WSSec]. In order to properly secure messages, the body and all relevant headers need to be included in the signature. Specifically, the <wscoor:CoordinationContext> header needs to be signed with the body and other key message headers in order to "bind" the two together.

In the event that a participant communicates frequently with a coordinator, it is RECOMMENDED that a security context be established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv] allowing for potentially more efficient means of authentication.

It is common for communication with coordinators to exchange multiple messages. As a result, the usage profile is such that it is susceptible to key attacks. For this reason it is strongly RECOMMENDED that the keys be changed frequently. This "re-keying" can be effected a number of ways. The following list outlines four common techniques:

- Attaching a nonce to each message and using it in a derived key function with the shared secret
- Using a derived key sequence and switch "generations"
- Closing and re-establishing a security context (not possible for delegated keys)
- Exchanging new secrets between the parties (not possible for delegated keys)

It should be noted that the mechanisms listed above are independent of the SCT and secret returned when the coordination context is created. That is, the keys used to secure the channel may be independent of the key used to prove the right to register with the activity.

The security context MAY be re-established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv]. Similarly, secrets can be exchanged using the mechanisms described in WS-Trust. Note, however, that the current shared secret SHOULD NOT be used to encrypt the new shared secret.

Derived keys, the preferred solution from this list, can be specified using the mechanisms described in WS-SecureConversation.
The following list summarizes common classes of attacks that apply to this protocol and identifies the mechanism to prevent/mitigate the attacks:

- **Message alteration** – Alteration is prevented by including signatures of the message information using WS-Security [WSSec].
- **Message disclosure** – Confidentiality is preserved by encrypting sensitive data using WS-Security.
- **Key integrity** – Key integrity is maintained by using the strongest algorithms possible (by comparing secured policies – see WS-Policy [WSPolicy] and WS-SecurityPolicy [WSSecPolicy]).
- **Authentication** – Authentication is established using the mechanisms described in WS-Security and WS-Trust [WSTrust]. Each message is authenticated using the mechanisms described in WS-Security [WSSec].
- **Accountability** – Accountability is a function of the type of and string of the key and algorithms being used. In many cases, a strong symmetric key provides sufficient accountability. However, in some environments, strong PKI signatures are required.
- **Availability** – Many services are subject to a variety of availability attacks. Replay is a common attack and it is RECOMMENDED that this be addressed as described in the next bullet. Other attacks, such as network-level denial of service attacks are harder to avoid and are outside the scope of this specification. That said, care should be taken to ensure that minimal processing be performed prior to any authenticating sequences.
- **Replay** – Messages may be replayed for a variety of reasons. To detect and eliminate this attack, mechanisms should be used to identify replayed messages such as the timestamp/nonce outlined in WS-Security [WSSec]. Alternatively, and optionally, other technologies, such as sequencing, can also be used to prevent replay of application messages.
