Quiz 5 (on Canvas)
Closed book / closed note

Ends at 1:08pm
Announcements

• Project 3 code due **Monday, March 20**, by 8pm to GitHub Classroom
• Project 3 artifact (panorama) due **Tuesday, March 21**, by 8pm to CMSX
• Project 4 to be released on Tuesday, March 21, due Friday, March 31 by 8pm
• Final exam is planned to be in class during the last lecture on Tuesday, May 9
Can we determine shape from lighting?

• Are these spheres?
  • Or just flat discs painted with varying color (albedo)?
  • There is ambiguity between shading and reflectance
• But still, as humans we can understand the shapes of these objects.
What we know: Stereo

Key Idea: use camera motion to compute shape
Next: Photometric Stereo

Key Idea: use pixel brightness to understand shape
Photometric Stereo

What results can you get?

Input (1 of 12)

Normals (RGB colormap)

Normals (vectors)

Shaded 3D rendering

Textured 3D rendering
Light

by Ted Adelson

• Readings
  – Szeliski, 2.2, 2.3
Light

• Readings
  – Szeliski, 2.2, 2.3
Properties of light

• Today
  – What is light?
  – How do we measure it?
  – How does light propagate?
  – How does light interact with matter?
Radiometry

- What determines the brightness of a pixel?
Radiometry

• What determines the brightness of a pixel?
Radiometry

• What determines the brightness of a pixel?
Radiometry

- What determines the brightness of a pixel?
What is light?

Electromagnetic radiation (EMR) moving along rays in space

- $R(\lambda)$ is EMR, measured in units of power (watts)
  - $\lambda$ is wavelength

Light field

- We can describe all of the light in the scene by specifying the radiation (or “radiance” along all light rays) arriving at every point in space and from every direction

The *plenoptic function* describes all of this light: $R(X, Y, Z, \theta, \phi, \lambda, t)$
Color perception

Electromagnetic radiation (EMR) moving along rays in space
- $R(\lambda)$ is EMR, measured in units of power (watts)
  - $\lambda$ is wavelength

Perceiving light
- How do we convert radiation into “color”?
- What part of the spectrum do we see?
Visible light

We “see” electromagnetic radiation in a range of wavelengths
Light spectrum

- The appearance of light depends on its power **spectrum**
  - How much power (or energy) at each wavelength

![](image1.png)!

- **daylight**
- **tungsten bulb**
- **fluorescent bulb**

Our visual system converts a light spectrum into “color”

- This is a rather complex transformation
The human visual system

• Color perception
  – Light hits the retina, which contains photosensitive cells
    • rods and cones
  – These cells convert the spectrum into a few discrete values
Density of rods and cones

• Rods and cones are *non-uniformly* distributed on the retina
  – Rods responsible for intensity, cones responsible for color
  – **Fovea**: Small region (1 or 2°) at the center of the visual field containing the highest density of cones (and no rods).
  – Less visual acuity in the periphery—many rods wired to the same neuron
Demonstrations of visual acuity

With one eye shut, at the right distance, all of these letters should appear equally legible (Glassner, 1.7).
Demonstrations of visual acuity

With left eye shut, look at the cross on the left. At the right distance, the circle on the right should disappear (Glassner, 1.8).
Brightness contrast and constancy

- The apparent brightness depends on the surrounding region
  - **brightness contrast**: a constant colored region seems lighter or darker depending on the surrounding intensity

- **brightness constancy**: a surface looks the same under widely varying lighting conditions.
Light response is nonlinear

• Our visual system has a large *dynamic range*
  – We can resolve both light and dark things at the same time
  – One mechanism for achieving this is that we sense light intensity on a *logarithmic scale*
    • an exponential intensity ramp will be seen as a linear ramp
  – Another mechanism is *adaptation*
    • rods and cones adapt to be more sensitive in low light, less sensitive in bright light.
Visual dynamic range

A piece of white paper can be 1,000,000,000 times brighter in outdoor sunlight than in a moonless night.

BUT in a given lighting condition, light perception ranges over only about two orders of magnitude.
Learning to See in the Dark

Visual dynamic range

If we were sensitive to this whole range all the time, we wouldn’t be able to discriminate lightness levels in a typical scene.

The visual system solves this problem by restricting the ‘dynamic range’ of its response to match the current overall or ‘ambient’ light level.
Color perception

• Three types of cones
  – Each is sensitive in a different region of the spectrum
    • but regions overlap
    • Short (S) corresponds to blue
    • Medium (M) corresponds to green
    • Long (L) corresponds to red
  – Different sensitivities: we are more sensitive to green than red
    • varies from person to person (and with age)
  – Colorblindness—deficiency in at least one type of cone
Rods and cones act as filters on the spectrum

- To get the output of a filter, multiply its response curve by the spectrum, integrate over all wavelengths
  - Each cone yields one number
- Q: How can we represent an entire spectrum with 3 numbers?
- A: We can’t! Most of the information is lost
  - As a result, two different spectra may appear indistinguishable
    - such spectra are known as metamers
Metamers

1. Combined light spectrum
Metamers

1. Combined light spectrum

2. Cone sensitivity (S, M, L)

3. Multiplication of 1 and 2
Metamers

1. Combined light spectrum
2. Cone sensitivity (S, M, L)
3. Multiplication of 1 and 2
4. Observed color (yellow)
What kind of bulb is it?

What color is the dress?

- White and gold?
- Black and blue?
Reflectance and Illumination In Popular Culture...

---

**The dress**

From Wikipedia, the free encyclopedia

For other uses, see [The Dress](#).

The dress is a photograph that became a viral internet sensation on 26 February 2015, when viewers disagreed over whether the dress pictured was coloured black and royal blue, or white and gold. The phenomenon revealed differences in human colour perception, which have been the subject of ongoing scientific investigations into neuroscience and vision science, with a number of papers published in peer-reviewed science journals.

The photo originated from a washed-out colour photograph of a dress posted on the social networking service Tumblr. Within the first week after the posting of the image, more than 10 million tweets mentioned the dress, using hashtags such as #thedress, #whiteandgold, and #whiteandblue. Although the colour of the actual dress was eventually confirmed as blue and black, the image prompted many discussions, with users debating their opinions on the colour and how they perceived the dress in the photograph as a certain colour.

Members of the scientific community began to investigate the photo for fresh insights into human colour vision.

The dress itself, which was identified as a product of the retailer Roman Originals, experienced a major surge in sales as a result of the incident. The retailer also produced a one-off version of the dress in white and gold as a charity campaign.

**Current Biology**
What color is the center ball?
What color is the center ball?
Perception summary

• The mapping from radiance to perceived color is quite complex!
  – We throw away most of the data
  – We apply a logarithm
  – Brightness affected by pupil size and adaptation of rods/cones
  – Brightness contrast and constancy effects

• The same is true for cameras
  – But we have tools to correct for these effects
    • (Computational Photography)
Cameras also see color

- Common technique is to place a mosaic of color filters (a *Bayer filter*) in front of the sensor.

- Colors are interpolated to create a full-resolution "demosaicked" color image.

[Link to Wikipedia: Bayer Filter](https://en.wikipedia.org/wiki/Bayer_filter)
Early color photography

• Prior to the invention of color film, Sergey Prokudin-Gorsky took three separate exposures with three different color filters.
Film has its own sensitivity

• “... the film of Lincoln’s era was sensitive only to blue and UV light, causing cheeks to appear dark, and overly emphasizing wrinkles by filtering out skin subsurface scatter which occurs mostly in the red channel. Hence, the deep lines and sharp creases that we associate with Lincoln’s face are likely exaggerated by the photographic process of the time.”
Questions?
Light transport
Light sources

• **Basic types**
  – point source
  – directional source
    • a point source that is infinitely far away
  – area source
    • a union of point sources

• More generally
  – a light field can describe *any* distribution of light sources

• What happens when light hits an object?
Modeling Image Formation

We need to reason about:

• How light interacts with the scene
• How a pixel value is related to light energy in the world

Track a “ray” of light all the way from light source to the sensor
Directional Lighting

- Key property: all rays are parallel
- Equivalent to an infinitely distant point source
Lambertian Reflectance

\[ I = N \cdot L \]

- Image intensity
- Surface normal direction
- Light direction

\[ \propto \cos(\text{angle between N and L}) \]
Materials - Three Forms

- Ideal diffuse (Lambertian)
- Ideal specular
- Directional diffuse
Reflectance

Three Forms

- Ideal diffuse (Lambertian)
- Directional diffuse
- Ideal specular
Ideal Diffuse Reflection

• Characteristic of multiple scattering materials
• An idealization but reasonable for matte surfaces
Lambertian Reflectance

1. Reflected energy is proportional to cosine of angle between L and N *(incoming)*

2. Measured intensity is viewpoint-independent *(outgoing)*
Lambertian Reflectance: Incoming

- Reflected energy is proportional to cosine of angle between L and N
Lambertian Reflectance: Incoming

- Reflected energy is proportional to cosine of angle between L and N
Lambertian Reflectance: Incoming

- Reflected energy is proportional to cosine of angle between L and N.

Light hitting surface is proportional to the cosine.
Lambertian appearance is view-independent

- Number of photons reflected to a given angle $\theta$ is proportional to $\cos(\theta)$.
Lambertian appearance is view-independent

- Number of photons reflected to a given angle $\theta$ is proportional to $\cos(\theta)$

  \[ B = B_0 \cos(\theta) \]

- But appearance is the same from every angle due to larger pixel footprint at larger angles

Lambert's cosine law: $B = B_0 \cos(\theta)$
Lambertian appearance is view-independent

- Number of photons reflected to a given angle $\theta$ is proportional to $\cos(\theta)$

$$B = B_0 \cos(\theta)$$

- But appearance is the same from every angle due to larger pixel footprint at larger angles

$$A_\theta \propto A_0 \frac{1}{\cos \theta}$$

Lambert's cosine law: $B = B_0 \cos(\theta)$
Lambertian appearance is view-independent

- Number of photons reflected to a given angle $\theta$ is proportional to $\cos(\theta)$

\[ B = B_0 \cos(\theta) \]

- But appearance is the same from every angle due to larger pixel footprint at larger angles

\[ A_\theta \propto A_0 \frac{1}{\cos \theta} \]

Lambert's cosine law: $B = B_0 \cos(\theta)$

Radiance (what eye sees) $\propto B_0 A_0 \frac{\cos(\theta)}{\cos(\theta)}$
1. Diffuse **albedo**: what fraction of incoming light is reflected?
   - Introduce scale factor $k_d$
2. Light intensity: how much light is arriving?
   - Compensate with camera exposure (global scale factor)
3. Camera response function
   - Assume pixel value is linearly proportional to incoming energy
     (perform radiometric calibration if not)
Albedo

Objects can have varying albedo and albedo varies with wavelength

Source: https://en.wikipedia.org/wiki/Albedo
A Single Image: Shape from shading

Suppose (for now) $k_d = 1$

$$I = k_d N \cdot L = N \cdot L = \cos \theta_i$$

You can directly measure angle between normal and light source

- Not quite enough information to compute surface shape
- But can be if you add some additional info, for example
  - assume a few of the normals are known (e.g., along silhouette)
  - constraints on neighboring normals—“integrability”
  - smoothness
- Hard to get it to work well in practice
  - plus, how many real objects have constant albedo?
  - But, deep learning can help
