Computation Graphs

Instructor: Yoav Artzi

From Practical Neural Networks for NLP / Chris Dyer,
Yoav Goldberg, Graham Neubig / EMNLP 2016

Computation Graphs

- The descriptive language of deep learning models
- Functional description of the required computation
- Can be instantiated to do two types of computation:
 - Forward computation
 - Backward computation

expression:

x

graph:

A **node** is a {tensor, matrix, vector, scalar} value

x

An **edge** represents a function argument (and also data dependency). They are just pointers to nodes.

A **node** with an incoming **edge** is a **function** of that edge's tail node.

A **node** knows how to compute its value and the *value of its derivative w.r.t each argument (edge) times a derivative of an arbitrary input* $\frac{\partial \mathcal{F}}{\partial f(\mathbf{u})}$.

expression:

$$\mathbf{x}^\top \mathbf{A}$$

graph:

Functions can be nullary, unary,
binary, ... n -ary. Often they are unary or binary.

expression:

$$\mathbf{x}^\top \mathbf{A} \mathbf{x}$$

graph:

Computation graphs are directed and acyclic (usually)

expression:

$$\mathbf{x}^\top \mathbf{A} \mathbf{x}$$

graph:

$$f(\mathbf{x}, \mathbf{A}) = \mathbf{x}^\top \mathbf{A} \mathbf{x}$$

$$\frac{\partial f(\mathbf{x}, \mathbf{A})}{\partial \mathbf{x}} = (\mathbf{A}^\top + \mathbf{A})\mathbf{x}$$
$$\frac{\partial f(\mathbf{x}, \mathbf{A})}{\partial \mathbf{A}} = \mathbf{x}\mathbf{x}^\top$$

expression:

$$\mathbf{x}^\top \mathbf{A} \mathbf{x} + \mathbf{b} \cdot \mathbf{x} + c$$

graph:

expression:

$$y = \mathbf{x}^\top \mathbf{A} \mathbf{x} + \mathbf{b} \cdot \mathbf{x} + c$$

graph:

variable names are just labelings of nodes.

Algorithms

- **Graph construction**
- **Forward propagation**
 - Loop over nodes in topological order
 - Compute the value of the node given its inputs
 - *Given my inputs, make a prediction (or compute an “error” with respect to a “target output”)*
- **Backward propagation**
 - Loop over the nodes in reverse topological order starting with a final goal node
 - Compute derivatives of final goal node value with respect to each edge’s tail node
 - *How does the output change if I make a small change to the inputs?*

Forward Propagation

graph:

Forward Propagation

graph:

Forward Propagation

graph:

Forward Propagation

graph:

Forward Propagation

graph:

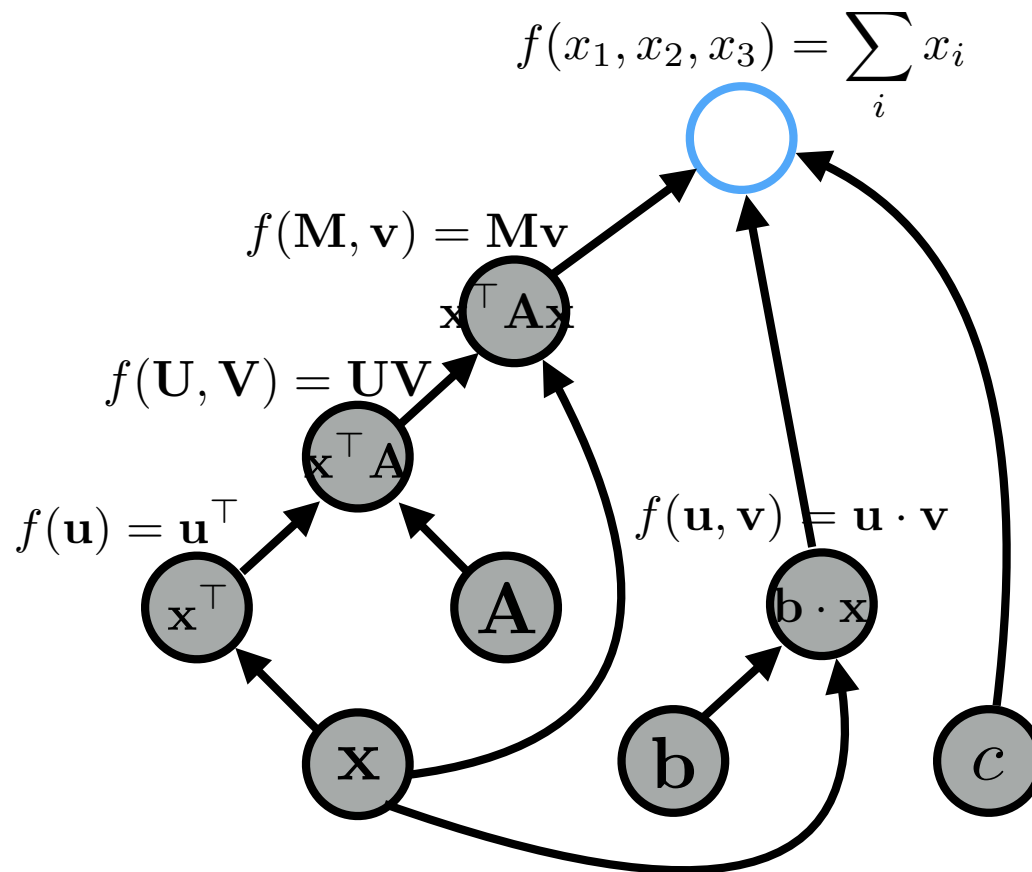

Forward Propagation

graph:

Forward Propagation

graph:

Forward Propagation

graph:

The MLP

$$\mathbf{h} = \tanh(\mathbf{W}\mathbf{x} + \mathbf{b})$$

$$\mathbf{y} = \mathbf{V}\mathbf{h} + \mathbf{a}$$

The MLP

$$\mathbf{h} = \tanh(\mathbf{W}\mathbf{x} + \mathbf{b})$$

$$\mathbf{y} = \mathbf{V}\mathbf{h} + \mathbf{a}$$

Constructing Graphs

Two Software Models

- **Static declaration**

- Phase 1: define an architecture
(maybe with some primitive flow control like loops and conditionals)
- Phase 2: run a bunch of data through it to train the model and/or make predictions

- **Dynamic declaration**

- Graph is defined implicitly (e.g., using operator overloading) as the forward computation is executed

Hierarchical Structure

Words

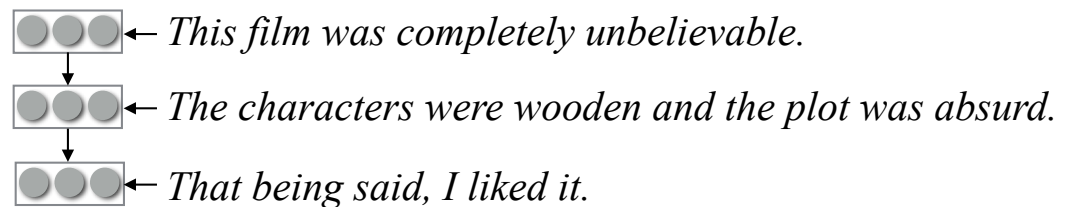

Sentences

Phrases

Documents

Static Declaration

- **Pros**

- Offline optimization/scheduling of graphs is powerful
- Limits on operations mean better hardware support

- **Cons**

- Structured data (even simple stuff like sequences), even variable-sized data, is complex
- You effectively learn a new programming language (“the Graph Language”) and you write programs in that language to process data.

- Examples: Torch, Theano, TensorFlow

Dynamic Declaration

- **Pros**

- Library is less invasive
- The forward computation is written in your favorite programming language with all its features, using your favorite algorithms
- Interleave construction and evaluation of the graph

- **Cons**

- Little time for graph optimization
- If the graph is static, effort can be wasted
- Examples: Chainer, *most automatic differentiation libraries*, **DyNet**

Dynamic Structure?

- Hierarchical structures exist in language
 - We might want to let the network reflect that hierarchy
 - Hierarchical structure is easiest to process with traditional flow-control mechanisms in your favorite languages
- Combinatorial algorithms (e.g., dynamic programming)
 - Exploit independencies to compute over a large space of operations tractably
