# Principled Programming 

Introduction to Coding in Any Imperative Language

Tim Teitelbaum

Emeritus Professor
Department of Computer Science
Cornell University

## Creative Representations

Choice of representations. Straightforward data representations are often effective and sufficient. However, creative representations can result in significant
improvements. We present four examples of innovative data representations:

- Tic-Tac-Toe
- Checkers
- The Eight Queens Problem
- The Ricocheting Bee-Bee Problem

The touchstone of a data representation is its utility in performing the needed operations.

Background: Tic-Tac-Toe is played on a 3-by-3 board. Two players take turns marking cells with "X" or " $O$ ". The objective is obtain 3 of your marks in a row, column, or diagonal.
Problem Statement: Write a program that plays Tic-Tac-Toe.

/* Update the data representation on a move by " $X$ " at $\langle r, c\rangle$. */

```
/* Test for a win by "X". */
```

The touchstone of a data representation is its utility in performing the needed operations.

## ／＊Data Representation．＊／

char T［］［］＝new char［3］［3］；／／〈＇＇，＇X＇，＇O＇〉 for 〈blank，＂X＂，＂O＂’．
／＊Update the data representation on a move by＂$X$＂at $\langle r, c\rangle$ ．＊／ $T[r][c]=$＇X＇；／／Mark T with＇X’ for＂$X$＂．
／＊Test for a win by＂X＂．＊／
if（

$$
\begin{aligned}
& \begin{array}{l}
T[0][0]==' X ' ~ \& \& ~ T[0][1]==' X ' ~ \& \& ~ T[0][2]==' X ' ~| | \\
T[1][0]==' X ' ~ \& \& ~ T[1][1]==' X ' ~ \& \& ~ T[1][2]==' X ' ~| |
\end{array} \\
& \text { T[0][0]=='X' \&\& T[1][1]=='X' \&\& T[2][2]=='X' || } \\
& \text { T[0][2]=='X' \&\& T[1][1]=='X' \&\& T[2][0]=='X' ) // "X" wins. }
\end{aligned}
$$

/* Data Representation. */
int T[][]$=$ new $\operatorname{int[3][3];~//~\langle 0,1,-1\rangle }$ for 〈blank,"X","0">.
/* Update the data representation on a move by " $X$ " at $\langle r, c\rangle$. */ $\mathrm{T}[\mathrm{r}][\mathrm{c}]=1$; // Mark T with 1 for " $X$ ".
/* Test for a win by "X". */
if $(T[0][0]+T[0][1]+T[0][1]==3 \quad| |$
$T[1][0]+T[1][1]+T[1][2]==3| |$
$\mathrm{T}[0][0]+\mathrm{T}[1][1]+\mathrm{T}[2][2]==3$ ||
$T[0][2]+T[1][1]+T[2][0]==3$ ) // " $X$ " wins.

|  | 0 |  | 1 |

Reflection: Because Tic-Tac-Toe is so simple, the efficiency of the above code is not really needed. It is intended to stretch your imagination, and exhibit principles that can lead to significant code improvement.

Background: Checkers is played on a 8-by-8 board, starting with the initial layout shown. The two players take turns makingA diagonal moves. In addition to the initial "men" shown, players can earn "queens". Because all moves are diagonal, only half the squares are used. No other rules are
 relevant for the purpose of this presentation.

Problem Statement: Write a program that plays Checkers.

/* Data Representation. */

The touchstone of a data representation is its utility in performing the needed operations.

/* Data Representation. */

```
/* 〈Blank, BlackMan, BlackQueen, RedMan, RedQueen` represented by \(\langle 0,1,2,-1,-2\rangle\). */
    int Board[][] = new int[8][8];
```

| 0 | -1 | 0 | -1 | 0 | -1 | 0 | -1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| -1 | 0 | -1 | 0 | -1 | 0 | -1 | 0 |
| 0 | -1 | 0 | -1 | 0 | -1 | 0 | -1 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| +1 | 0 | +1 | 0 | +1 | 0 | +1 | 0 |
| 0 | +1 | 0 | +1 | 0 | +1 | 0 | +1 |
| +1 | 0 | +1 | 0 | +1 | 0 | +1 | 0 |

This representation requires 64*32 bits.

The touchstone of a data representation is its utility in performing the needed operations.

/* Data Representation. */
/* 〈Blank, BlackMan, BlackQueen, RedMan, RedQueen〉 represented by $\langle 0,1,2,-1,-2\rangle$. */ int Board[] = new int[32];

Number the used squares $0 . .31$ and adopt a
1-dimensional representation indexed by those numbers. This requires only half the space, i.e., $32 * 32$ bits.

The touchstone of a data representation is its utility in performing the needed operations.

|  | 28 |  | 29 |  | 30 |  | 31 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 24 |  | 25 |  | 26 |  | 27 |  |
|  | 20 |  | 21 |  | 22 |  | 23 |
| 16 |  | 17 |  | 18 |  | 19 |  |
|  | 12 |  | 13 |  | 14 |  | 15 |
| 8 |  | 9 |  | 10 |  | 11 |  |
|  | 4 |  | 5 |  | 6 |  | 7 |
| 0 |  | 1 |  | 2 |  | 3 |  |

## /* Data Representation. */

/* 〈Blanks, BlackMen, BlackQueens, RedMen, RedQueens〉 represented by 5 separate Boolean arrays. */ boolean Blanks[] = new boolean[32]; boolean BlackMen[] = new boolean[32]; boolean BlackQueens[] = new boolean[32]; boolean RedMen[] = new boolean[32]; boolean RedQueens[] = new boolean[32];

Because there are only 5 things to represent, the same information can be stored in 5 boolean arrays. Thus, only $5 * 32$ bits are required, i.e., 5/64 of the original.

Blanks
all targets of forward-right moves
and obtain the positions of all blank squares reachable by BlackMen in a forward-right diagonal move.

The touchstone of a data representation is its utility in performing the needed
operations.

History and Serendipity: Arthur Samuels, a founder of the field of Machine Learning, wrote a Checkers playing program in the 1950s, for which he invented the above representation.

At that time, the fundamental word length of computers was 36 bits. An operation like Shift-Right-5 could be performed in a single machine instruction, and so too could an operation like bitwise-logical-and. Thus, the target of all forward-right moves by BlackMen to a vacant square could be performed in just 2 machine instructions!

Shortly thereafter, IBM changed to 32-bit words, which eliminated the possibility of representing phantom squares in words, and the efficiency of uniform shifts of them to compute possible moves in parallel.

Words are now 64-bits (or more), and so the representation is viable once again.
The touchstone of a data representation is its utility in performing the needed operations.

Background: Chess is played on a 8-by-8 board. A Queen can move or capture at any distance vertically, horizontally, or diagonally. It is possible to place eight Queens on the board so that no two are on the same row, column, or diagonal..

Problem Statement: Write a program that finds a layout that

## /* Data Representation. */

Choose representations that by design do not have nonsensical configurations.
/* Data Representation. */

int $R[]=$ new int[8]; // $R[c]$ is $r$ if Queen in $\langle r, c\rangle$.

Why not choose a representation (with $8^{\wedge} 8$ states) in which two-in-the-samerow cannot even be expressed.

Not a solution because there are two Queens in same row.

Choose representations that by design do not have nonsensical configurations.
/* Data Representation. */

But why choose a representation (with $8^{\wedge} 8$ states) that allows two-in-the-same column to be expressed?

Require $R$ to be a permutation of $1,2,3,4,5,6,7,8$.

Tra Choose representations that by design do not have nonsensical configurations.
/* Data Representation. */

The failing configuration (above) cannot be expressed as a permutation of 1,2,3,4,5,6,7,8.

Choose representations that by design do not have nonsensical configurations.
/* Solve the Eight Queens problem. */
static void main() \{
/* $\mathrm{R}[\mathrm{c}]$ is r if Queen in $\langle\mathrm{r}, \mathrm{c}\rangle .{ }^{*} /$
int $R[]=\{0,1,2,3,4,5,6,7\} ;$
/* Consider each permutation of R until one is found that represents a solution. (At least one such permutation is known to exist.) */ while ( condition ) NextPermutation(R);
/* Output solution R. */
\} /* main */
The touchstone of a data representation is its utility in performing the needed operations.
/* Solve the Eight Queens problem. */
static void main() \{
/* $\mathrm{R}[\mathrm{c}]$ is r if Queen in $\langle r, c\rangle .{ }^{*} /$
int $R[]=\{0,1,2,3,4,5,6,7\} ;$
/* Consider each permutation of R until one is found that represents a solution. (At least one such permutation is known to exist.) */ while ( hasSameDiagonal(R) ) NextPermutation(R);
/* Output solution R. */
\} /* main */
The touchstone of a data representation is its utility in performing the needed operations.

Positive diagonal index: row+column

Negative diagonal index: column-row+7
int c = 0;
while ( c<8 \&\& !PosDiag[R[c]+c] \&\& !NegDiag[c-R[c]+7] ) \{
PosDiag[R[c]+c] = true; NegDiag[c-R[c]+7] = true;
c++;
\}
return c!=8;
\} /* hasSameDiagonal */

Iterate through the 8 queens until the first that occurs on an already-occupied diagonal. If no such queen is found, then the permutation represents a solution.

Commentary. Who would have guessed that the Eight Queens Problem reduces to:

```
/* Update R[0..7] to be the next permutation of 1,2,3,4,5,6,7,8
    in a cycle of all 8! Such permutations. */
static void NextPermutation( int R[] ) {
```

\}
which is left as a (not so easy) exercise.

Background. A square tin box measuring one foot on each side has a slit of size d centered on one side. Insert a bee-bee gun at the center of the slit at angle $\Theta$, and shoot. The bee-bee ricochets off sides, one after another. On each ricochet, the angle of reflection is equal to the angle of incidence.
Problem Statement. Write a program that inputs $d$ and $\Theta$, and outputs the total distance the bee-bee travels before it exits.

Background. A square tin box measuring one foot on each side has a slit of size d centered on one side. Insert a bee-bee gun at the center of the slit at angle $\Theta$, and shoot. The bee-bee ricochets off sides, one after another. On each ricochet, the angle of reflection is equal to the angle of incidence.
Problem Statement. Write a program that inputs $d$ and $\Theta$, and outputs the total distance the bee-bee travels before it exits.

Problem Reduction. Allow the bee-bee to break through the wall of the box, and proceed in a straight line trajectory.

Problem Reduction. Consider the plane to be tiled with reflections of the box.

əәg-əәg ภิน!ఛəЧગОગ!У

Problem Reduction. Add Cartesian coordinates with origin centered in the middle of the slit of the lower-leftmost box.

Ricocheting Bee-Bee

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$.

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$.

Ricocheting Bee-Bee

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$.

Ricocheting Bee-Bee

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$.

Ricocheting Bee-Bee

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$.

Ricocheting Bee-Bee

Problem Reduction. The slit replicas are on even values of $y$, centered on integer values of $x$, etc.

Ricocheting Bee-Bee

Problem Reduction. We seek the smallest (even) y such that the trajectory falls within $\mathrm{d} / 2$ of the center of a slit replica.

Problem Reduction. We seek the smallest (even) y such that the trajectory falls within $\mathrm{d} / 2$ of the center of a slit replica.

Problem Reduction. We seek the smallest (even) y such that the trajectory falls within $\mathrm{d} / 2$ of the center of a slit replica.

Problem Reduction. We seek the smallest (even) y such that the trajectory falls within $\mathrm{d} / 2$ of the center of a slit replica.

where

Problem Reduction. Output the length of the trajectory for that $y$ and the corresponding $x$.

int $y=2$;
while ( Math.abs(x(y,theta)-Math.round(x(y,theta)))>=d/2 ) y = y+2;
System.out.println( Hypotenuse( $x(y, t h e t a), y)$ );
where
/* Return length of hypotenuse of triangle with sides $x$ and $y . * /$ static double Hypotenuse( double $x$, double $y$ ) \{ return Math.sqrt ( $x^{*} x+y+y$ ); \} /* Hypotenuse */

static double $x$ (double $y$, double theta) \{
〈compute $x$ from $y$ and theta〉
\} /* x */

static double $x$ (double $y$, double theta) \{

©
double d = in.nextDouble();
double theta $=$ in. nextDouble();
int $y=2$;
while ( Math.abs(x(y,theta)-Math.round(x(y,theta)))>=d/2 ) y = y+2;
System.out.println( Hypotenuse( $x(y, t h e t a), y)$ );
\}

[^0]:    N.B. The implementation of a programming language does not necessarily implement boolean as 1 bit, but in principle it could.

[^1]:    The touchstone of a data representation is its utility in performing the needed operations.
