Closures

Prof. Clarkson
Fall 2015

Today's music: Selections from *Doctor Who* soundtracks by Murray Gold

Review

Previously in 3110:

- Interpreters: ASTs, evaluation, parsing
- Formal syntax: BNF
- Formal semantics:
  - dynamic: small-step substitution model
  - static semantics

Today:

- More formal dynamic semantics: large-step, environment model

Prelim 1

- Next Thursday, 5:30-7 and 7:30-9
- For further details, see Piazza @852

Review: big-step semantics

- *Big-step semantics*: we model just the reduction from the original expression to the final value
- Judgement is written **`e ==> v`**

  read as **`e`** *takes a big step to* **`v`**
- **Goal: `e ==> v`** if and only if **`e -->* v`**

Variables

- What does a variable name evaluate to?

```
x ==> ???
```

- Trick question: we don't have enough information to answer it
- Need to know what value variable was *bound* to
  - e.g., `let x = 2 in x+1`
  - e.g., `(fun x -> x+1) 2`
  - e.g., `match 2 with x -> x+1`
  - All evaluate to **3**, but we reach a point where we need to know binding of **x**
- Until now, we've never needed this, because we always **substituted** before we ever get to a variable name

Variables

OCaml doesn't actually do substitution

```
(fun x -> 42) 0
```

waste of runtime resources to do substitution inside 42

Instead, OCaml lazily substitutes by maintaining *dynamic environment*

Dynamic environment

- Dictionary of bindings of all current variables
- Changes throughout evaluation:
  - No bindings at $:

```
$ let x = 42 in
  let y = false in
  e
```

  - One binding **[x=42]** at $:

```
  let x = 42 in
$ let y = false in
  e
```

  - Two bindings **[x=42,y=false]** at $:

```
  let x = 42 in
  let y = false in
$ e
```

Variable evaluation

To evaluate `x` in environment `env`

Look up value `v` of `x` in `env`

Return `v`

Type checking guarantees that variable is bound, so we can't ever fail to find a binding in dynamic environment

Evaluation judgement

Extended notation:

`<env, e> ==> v`

Meaning: in dynamic environment **`env`**, expression **`e`** takes a big step to value **`v`**

`<env, e>` is called a *machine configuration*

Variable evaluation

```
<env, x> ==> v
   if v = env(x)
```

`env(x)` :

- meaning: the value to which **`env`** binds **`x`**
- think of it as looking up **`x`** in dictionary **`env`**

Redo: evaluation with environment

```
<env, v> ==> v

<env, e1 + e2> ==> v
  if <env, e1> ==> i1
  and <env, e2> ==> i2
  and v is the result of
    primitive operation i1+i2
```

Let expressions

To evaluate `let x = e1 in e2` in environment **`env`**

Evaluate the binding expression **`e1`** to a value **`v1`** in environment **`env`**

```
<env, e1> ==> v1
```

Extend the environment to bind **`x`** to **`v1`**

```
env' = env[x->v1]
```
new notation

Evaluate the body expression **`e2`** to a value **`v2`** in extended environment **`env'`**

```
<env', e2> ==> v2
```

Return `v2`

Let expression evaluation rule

```
<env, let x=e1 in e2> ==> v2
   if <env, e1> ==> v1
   and <env[x->v1], e2> ==> v2
```

Example: (let `[]` be the empty environment)

`<[],let x = 42 in x> ==> 42`

Because...

- **`<[], 42> ==> 42`**
- and **`<[][x->42], x> ==> 42`**
  - Because **`[x=42](x)=42`**

Function values v1.0

Anonymous functions are values:

```
<env, fun x -> e> ==> fun x -> e
```

Function application v1.0

To evaluate `e1 e2` in environment **`env`**

Evaluate `e1` to a value **`v1`** in environment **`env`**

```
<env,e1> ==> v1
```

Note that **`v1`** *must be a function value* **`fun x -> e`**
because function application type checks

Evaluate `e2` to a value **`v2`** in environment **`env`**

```
<env,e2> ==> v2
```

Extend environment to bind formal parameter **`x`** to actual value **`v2`**

```
env' = env[x->v2]
```

Evaluate body **`e`** to a value **`v`** in environment **`env'`**

```
<env',e> ==> v
```

Return `v`

Function application rule v1.0

```
<env,e1 e2> ==> v
```
if `<env,e1> ==> fun x -> e`
and `<env,e2> ==> v2`
and `<env[x->v2],e> ==> v`

Example:

```
<[],(fun x -> x) 1> ==> 1
```
b/c `<[],fun x -> x> ==> fun x -> x`
and `<[],1> ==> 1`
and `<[][x->1], x> ==> 1`

Scope

```
let x = 1 in
let f = fun y -> x in
let x = 2 in
  f 0
```

What does our dynamic semantics say it evaluates to?

What does OCaml say?

What do YOU say?

Question

What do you think this expression should evaluate to?

```
let x = 1 in
let f = fun y -> x in
let x = 2 in
  f 0
```

A. 1

B. 2

Scope: OCaml

What does OCaml say this evaluates to?

```
let x = 1 in
let f = fun y -> x in
let x = 2 in
   f 0
- : int = 1
```

Scope: our semantics

What does our semantics say?

```
let x = 1 in
[x=1] let f = fun y -> x in
[x=1,f=(fun y->x)] let x = 2 in
   [x=2,f=(fun y->x)] f 0
```

<[x=2,f=(fun y->x)], f 0> ==> ???

1. Evaluate **f** to a value, i.e., **fun y->x**
2. Evaluate **0** to a value, i.e., **0**
3. Extend environment to map parameter:
   [x=2, f=(fun y->x), y=0]
4. Evaluate body **x** in that environment
5. Return **2**

2 <> 1

Why different answers?

Two different rules for variable scope:

- Rule of *dynamic scope* (our semantics so far)
- Rule of *lexical scope* (OCaml)

Dynamic scope

Rule of dynamic scope: The body of a function is evaluated in the current dynamic environment at the time the function is **called**, not the old dynamic environment that existed at the time the function was defined.

- Causes our semantics to use latest binding of **x**
- Thus return **2**

Lexical scope

Rule of lexical scope: The body of a function is evaluated in the old dynamic environment that existed at the time the function was **defined**, not the current environment when the function is called.

- Causes OCaml to use earlier binding of `x`
- Thus return `1`

Lexical scope

Rule of  on is evaluate hat existed d, not the curr is called.

– Cause

– Thus

Lexical vs. dynamic scope

- Consensus after decades of programming language design is that **lexical scope is the right choice**
  - it supports the Principle of Name Irrelevance
  - programmers free to change names of local variables
  - type checker can prevent more run-time errors

- Dynamic scope is useful in some situations
  - Some languages use it as the norm (e.g., Emacs LISP, LaTeX)
  - Some languages have special ways to do it (e.g., Perl, Racket)
  - But most languages just don't have it

- Exception handling resembles dynamic scope:
  - `raise e` transfers control to the "most recent" exception handler
  - like how dynamic scope uses "most recent" binding of variable

Implementing time travel

Q: How can functions be evaluated in old environments?

A: The language implementation keeps old environments around as necessary

Implementing time travel

A function value is really a data structure that has two parts:

- The code (obviously), an expression **`e`**
- The environment **`env`** that was current when the function was defined
- We'll notate that data structure as **`{e | env}`**

`{e | env}` is like a pair

- But you cannot write OCaml syntax to access the pieces
- And you cannot directly write it in OCaml syntax

This data structure is called a *function closure*

("and that my friend is what they call closure")

Function application v2.0

orange = changed from v1.0

To evaluate `e1 e2` in environment **`env`**
Evaluate `e1` to a value **`v1`** in environment **`env`**

```
<env,e1> ==> v1
```

Note that **`v1`** *must be a function closure* `{fun x -> e | defenv}`

Evaluate `e2` to a value **`v2`** in environment **`env`**

```
<env,e2> ==> v2
```

Extend closure environment to bind formal parameter **`x`** to actual value **`v2`**

```
env' = defenv[x->v2]
```

Evaluate body **`e`** to a value **`v`** in environment **`env'`**

```
<env',e> ==> v
```

Return `v`

Function application rule v2.0

```
<env, e1 e2> ==> v
```

if `<env, e1> ==> {fun x -> e | defenv}`

and `<env, e2> ==> v2`

and `<defenv[x->v2], e> ==> v`

Function values v2.0

Anonymous functions **`fun x-> e`** are closures:

```
<env, fun x -> e>
==> {fun x -> e | env}
```

Closures in OCaml

```
clarkson@chardonnay ~/share/ocaml-4.02.0/
bytecomp
$ grep Kclosure *.ml
bytegen.ml:          (Kclosure(lbl, List.length
fv) :: cont)
bytegen.ml:            (Kclosurerec(lbls,
List.length fv) ::
emitcode.ml:   | Kclosure(lbl, n) -> out
opCLOSURE; out_int n; out_label lbl
emitcode.ml:   | Kclosurerec(lbls, n) ->
instruct.ml:   | Kclosure of label * int
instruct.ml:   | Kclosurerec of label list * int
printinstr.ml:   | Kclosure(lbl, n) ->
printinstr.ml:   | Kclosurerec(lbls, n) ->
```

Closures in Java

- Nested classes can simulate closures
  - Used everywhere for Swing GUI! http://docs.oracle.com/javase/tutorial/uiswing/events/generalrules.html#innerClasses
  - You've done it yourself already in 2110
- Java 8 adds higher-order functions and closures

Closures in C

- In C, a *function pointer* is just a code pointer, period. No environment.
- To simulate closures, a common **idiom**:

  Define function pointers to take an extra, explicit environment argument
  - But without generics, no good choice for type of list elements or the environment
  - Use **`void*`** and various type casts…
- From Linux kernel: http://lxr.free-electrons.com/source/include/linux/kthread.h#L13

Upcoming events

- [today] A3 due
- [Mon,Tue] Fall Break
- [Wed] Prelim 1 review
- [Thu am] lecture cancelled
- [Thu pm] Prelim 1 at 5:30 and 7:30 pm

This is closure.

THIS IS 3110
