

CS1110 1 April 2010

Developing array algorithms. Reading: 8.3.8.5

Important point: how we create the invariant, as a picture

Haikus (5-7-5) seen on Japanese computer monitors

Yesterday it worked.	Serious error.
Today it is not working.	All shortcuts have disappeared.
Windows is like that.	Screen. Mind. Both are blank.
A crash reduces	The Web site you seek
Your expensive computer	Cannot be located, but
To a simple stone.	Countless more exist.
Three things are certain:	Chaos reigns within.
Death, taxes, and lost data.	Reflect, repent, and reboot.
Guess which has occurred?	Order shall return.

1

Developing algorithms on arrays

We develop several important algorithms on arrays.

With each, we specify the algorithm by giving its precondition and postcondition as pictures.

Then, draw the invariant by drawing another picture that “generalizes” the precondition and postcondition, since the invariant is true at the beginning and at the end.

Four loopy questions —memorize them:

1. How does loop start (how to make the invariant true)?
2. When does it stop (when is the postcondition true)?
3. How does repetend make progress toward termination?
4. How does repetend keep the invariant true?

2

Horizontal notation for arrays, strings, Vectors

Example of an assertion about an array b . It asserts that:

1. $b[0..k-1]$ is sorted (i.e. its values are in ascending order)
2. Everything in $b[0..k-1]$ is \leq everything in $b[k..b.length-1]$

Given the index h of the First element of a segment and the index k of the element that Follows the segment, the number of values in the segment is $k - h$. $b[h..k-1]$ has $k - h$ elements in it.

3

Invariant as picture: Combining pre- and post-condition

Finding the minimum of an array. Given array b satisfying precondition P , store a value in x to truthify postcondition Q :

$P: b$ and $n \geq 0$ (values in $0..n$ are unknown)

$Q: b$

3

The invariant as picture: Combining pre- and post-condition

Put negative values before nonnegative ones. given precondition P :

$P: b$ (values in $0..n-1$ are unknown)

Swap the values of $b[0..n-1]$ and store in k to truthify Q :

$Q: b$ (values in $0..k-1$ are < 0 , values in $k..n-1$ are > 0)

4

The invariant as picture: Combining pre- and post-condition

Dutch national flag. Swap values of $0..n-1$ to put the reds first, then the whites, then the blues. That is, given precondition P , swap value of $b[0..n]$ to truthify postcondition Q :

$P: b$ (values in $0..n-1$ are unknown)

$Q: b$

5

How to make invariant look like initial condition

pre b

0	?	n
---	---	---

inv b

0	j	k	l	n
reds	whites	?	blues	

1. **Make red, white, blue section empty**: use formulas for no. of values in these sections, set j, k, l so that they have 0 elements.

2. Compare precondition with invariant. E.g. in precondition, 0 marks first unknown. In invariant, k marks first unknown. Therefore, k and 0 must be the same.

4

Partition algorithm: Given an array $b[h..k]$ with some value x in $b[h]$:

P: b

h	x	?	k
---	---	---	---

Swap elements of $b[h..k]$ and store in j to truthify P:

Q: b

h	<= x	j	x	>= x	k
---	------	---	---	------	---

change: b

h	3 5 4 1 6 2 3 8 1	k
---	-------------------	---

into b

h	1	2	1	3	5	4	6	3	8	k
---	---	---	---	---	---	---	---	---	---	---

or b

h	1	2	3	1	3	4	5	6	8	k
---	---	---	---	---	---	---	---	---	---	---

x is called the **pivot value**.

x is not a program variable; x just denotes the value initially in $b[h]$.

6

Linear search (for value known to be in array)

Vague spec.: Find first occurrence of v in $b[h..k-1]$, which is known to be there.

Better spec.: Store an integer in i to truthify postcondition Q:

Q: 1. v is not in $b[h..i-1]$
2. $v = b[i]$

precondition P: b

h	v is in here	k
---	--------------	---

postcondition Q: b

h	v not here	i	v	?	k
---	------------	---	---	---	---

Can't simply combine P and Q because position of v not known initially. But we can just delete value v from Q:

invariant Q: b

h	v not here	i	v is in here	k
---	------------	---	--------------	---

7

Linear search

Vague spec.: Find first occurrence of v in $b[h..k-1]$.

Better spec.: Store an integer in i to truthify postcondition Q:

Q: 1. v is not in $b[h..i-1]$
2. $i = k$ OR $v = b[k]$

P: b

h	v is in here	k
---	--------------	---

Q: b

h	x not here	i	x	?	k
---	------------	---	---	---	---

OR

b

h	x not here	k
---	------------	---

8

Binary search: Vague spec: Look for v in **sorted** array segment $b[h..k]$.

Better spec:

Precondition P: $b[h..k]$ is sorted (in ascending order).

Store in i to truthify:

Postcondition Q: $b[h..i] \leq v$ and $v < b[i+1..k]$

Below, the array is in non-descending order:

P: b

h	?	k
---	---	---

Q: b

h	<= v	i	> v	k
---	------	---	-----	---

Called **binary search** because each iteration of the loop cuts the array segment still to be processed in half

9

Reversal: Reverse the elements of array segment $b[h..k]$.

precondition P: b

h	not reversed	k
---	--------------	---

postcondition Q: b

h	reversed	k
---	----------	---

Change: b

h	1 2 3 4 5 6 7 8 9 9 9 9	k
---	-------------------------	---

into b

h	9 9 9 9 8 7 6 5 4 3 2 1	k
---	-------------------------	---

10

Remove adjacent duplicates

change:

0	n
b	1 2 2 4 2 2 7 8 9 9 9 9

into

0	h	n
b	1 2 4 2 7 8 9	8 9 9 9 9

don't care what is
in $b[k+1..n]$

Truthify:

 $b[0..h] =$ initial values in $b[0..n]$ but with adj dups removed

Precondition P: b

h	k
?	

Postcondition Q: b

h	i	k
initial values of $b[0..k]$ with no duplicates		unchanged

11

Check whether two arrays are equal

/** = "b and c are equal" (both null or both contain
arrays whose elements are the same) */

public static boolean equals(**int[]** b, **int[]** c) {

}

14
